<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u></p> <p style="padding-left: 20px;"><u>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</u></p> <p style="padding-left: 20px;"><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p style="padding-left: 20px;"><u>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</u></p> <p style="padding-left: 20px;"><u>transmitting a transmission that contains said at</u></p>	<p>6. In a signal processing system,</p> <p style="padding-left: 20px;">a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means,</p> <p style="padding-left: 20px;">a matrix switch means for receiving said programming from said receiver/distributor means and for outputting selected portions of said received programming to a broadcast transmission means and/or a recording device operatively connected to said broadcast transmission means,</p> <p style="padding-left: 20px;">a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detected said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p style="padding-left: 20px;">a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p style="padding-left: 20px;">a processor means for controlling the output functions of said matrix switch means and the transfer functions of said storage/transfer means.</p>

least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,
wherein said method delivers said video graphic presentation.

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 5,109,414, Claim 6
<p>177. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p><u>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</u></p> <p><u>delivering said received first completed full-screen video graphic image to a transmitter;</u></p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>transferring said one or more instruct signals to said transmitter; and</u></p> <p><u>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one</u></p>	<p>6. In a signal processing system,</p> <p>a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distributor means and for outputting selected portions of said received programming to a broadcast transmission means and/or a recording device operatively connected to said broadcast transmission means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detected said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the output functions of said matrix switch means and the transfer functions of said storage/transfer means.</p>

<u>receiver station,</u> <u>wherein said method delivers said video graphic presentation.</u>	
--	--

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 5,109,414, Claim 6
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</u> <u>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> detecting said at least a first discrete signal; passing said at least a first discrete signal to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>6. In a signal processing system, a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distributor means and for outputting selected portions of said received programming to a broadcast transmission means and/or a recording device operatively connected to said broadcast transmission means, a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detected said control signals in a predetermined frequency range or at a predetermined location within said programming, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the output functions of said matrix switch means and the transfer functions of said storage/transfer means.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus.

Application Claim 56	U.S. Pat. No. 5,109,414, Claim 7
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p>and</p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>7. In a signal processing system,</p> <p>a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distributor means and for directing selected portions of said received programming to a broadcast transmission means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 5,109,414, Claim 7
<p>75. <u>A method of delivering a video presentation at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p style="padding-left: 40px;"><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</u></p> <p style="padding-left: 40px;">transferring said downloadable processor instructions to a transmitter;</p> <p style="padding-left: 40px;">receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</p> <p style="padding-left: 40px;">transferring said at least one control signal to said transmitter; and</p> <p style="padding-left: 40px;">transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	<p>7. In a signal processing system,</p> <p style="padding-left: 40px;">a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means,</p> <p style="padding-left: 40px;">a matrix switch means for receiving said programming from said receiver/distributor means and for directing selected portions of said received programming to a broadcast transmission means,</p> <p style="padding-left: 40px;">a control signal detector means for detecting control signals respecting said programming and transferring said control signals to storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p style="padding-left: 40px;">a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p style="padding-left: 40px;">a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means.</p>

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 5,109,414, Claim 7
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</u></p> <p><u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u></p> <p>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</p> <p>transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>7. In a signal processing system,</p> <p>a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distributor means and for directing selected portions of said received programming to a broadcast transmission means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 5,109,414, Claim 7
<p>84. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</u></p> <p style="padding-left: 40px;"><u>receiving video at a transmitter station;</u> <u>delivering said video to a transmitter;</u> <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and <u>transmitting said video and said first discrete signal to said at least one receiver station.</u></p>	<p>7. In a signal processing system,</p> <p style="padding-left: 40px;">a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distributor means and for directing selected portions of said received programming to a broadcast transmission means, a control signal detector means for detecting control signals respecting said programming and transferring said control signals to storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means.</p>

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 5,109,414, Claim 7
<p>93. <u>A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</u></p> <p>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal;</p> <p>detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission;</p> <p>passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor;</p> <p><u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>7. In a signal processing system,</p> <p>a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distributor means and for directing selected portions of said received programming to a broadcast transmission means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means.</p>

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 5,109,414, Claim 7
<p>110. <u>A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</u></p> <p><u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u></p> <p>transferring said at least said first discrete signal to at least one transmitter;</p> <p><u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u></p> <p>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>7. In a signal processing system,</p> <p>a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distributor means and for directing selected portions of said received programming to a broadcast transmission means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means.</p>

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 5,109,414, Claim 7
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u></p> <p style="padding-left: 40px;"><u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u></p> <p style="padding-left: 40px;">receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</p> <p style="padding-left: 40px;">transferring said at least one control signal to said at least one origination transmitter before a specific time; and</p> <p style="padding-left: 40px;">transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	<p>7. In a signal processing system,</p> <p style="padding-left: 40px;">a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means,</p> <p style="padding-left: 40px;">a matrix switch means for receiving said programming from said receiver/distributor means and for directing selected portions of said received programming to a broadcast transmission means,</p> <p style="padding-left: 40px;">a control signal detector means for detecting control signals respecting said programming and transferring said control signals to storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p style="padding-left: 40px;">a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p style="padding-left: 40px;">a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means.</p>

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 5,109,414, Claim 7
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u></p> <p style="padding-left: 40px;"><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p style="padding-left: 40px;">transferring said at least one instruct signal to at least one transmitter;</p> <p style="padding-left: 40px;"><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and</u></p> <p style="padding-left: 40px;">transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	<p>7. In a signal processing system,</p> <p style="padding-left: 40px;">a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means,</p> <p style="padding-left: 40px;">a matrix switch means for receiving said programming from said receiver/distributor means and for directing selected portions of said received programming to a broadcast transmission means,</p> <p style="padding-left: 40px;">a control signal detector means for detecting control signals respecting said programming and transferring said control signals to storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p style="padding-left: 40px;">a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p style="padding-left: 40px;">a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means.</p>

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 5,109,414, Claim 7
<p>142. <u>A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</u> receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal; detecting said at least a first discrete signal and said at least one control signal in said information transmission; passing said detected at least a first discrete signal to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; <u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>7. In a signal processing system, a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distributor means and for directing selected portions of said received programming to a broadcast transmission means, a control signal detector means for detecting control signals respecting said programming and transferring said control signals to storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 5,109,414, Claim 7
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u> receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to <u>processor instructions comprising said organized information,</u> based on said step of organizing; generating a signal based on said processor instructions; and <u>outputting at least a portion of said video presentation based on said generated signal.</u></p>	<p>7. In a signal processing system, a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distributor means and for directing selected portions of said received programming to a broadcast transmission means, a control signal detector means for detecting control signals respecting said programming and transferring said control signals to storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means.</p>

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 5,109,414, Claim 7
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</u></p> <p style="padding-left: 40px;">receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</p> <p style="padding-left: 40px;">transferring said downloadable processor instructions to a transmitter;</p> <p style="padding-left: 40px;"><u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p style="padding-left: 40px;">transferring said one or more control signals to said transmitter; and</p> <p style="padding-left: 40px;">transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>7. In a signal processing system,</p> <p style="padding-left: 40px;">a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means,</p> <p style="padding-left: 40px;">a matrix switch means for receiving said programming from said receiver/distributor means and for directing selected portions of said received programming to a broadcast transmission means,</p> <p style="padding-left: 40px;">a control signal detector means for detecting control signals respecting said programming and transferring said control signals to storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p style="padding-left: 40px;">a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p style="padding-left: 40px;">a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means.</p>

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 5,109,414, Claim 7
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</u></p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</p> <p>transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>7. In a signal processing system,</p> <p>a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distributor means and for directing selected portions of said received programming to a broadcast transmission means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 5,109,414, Claim 7
<p>162. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of discrete signals, said method comprising the steps of:</u> <u>receiving a video image at a transmitter station;</u> <u>delivering said video image to a transmitter;</u> <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> <u>transferring said at least said first of said plurality of discrete signals to said transmitter; and</u> <u>transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</u></p>	<p>7. In a signal processing system, a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distributor means and for directing selected portions of said received programming to a broadcast transmission means, a control signal detector means for detecting control signals respecting said programming and transferring said control signals to storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus.

Application Claim 167	U.S. Pat. No. 5,109,414, Claim 7
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</u> <u>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal of said downloadable code;</u> <u>passing said at least a first discrete signal of said downloadable code to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>7. In a signal processing system, a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distributor means and for directing selected portions of said received programming to a broadcast transmission means, a control signal detector means for detecting control signals respecting said programming and transferring said control signals to storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means.</p>

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 5,109,414, Claim 7
<p>171. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:</u></p> <p><u>receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</u></p> <p><u>transferring said at least one discrete signal to a transmitter;</u></p> <p><u>receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;</u></p> <p><u>transferring said one or more control signals to said transmitter; and</u></p> <p><u>transmitting a transmission comprising said at least one discrete signal and said one or more control signals,</u></p>	<p>7. In a signal processing system,</p> <p>a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distributor means and for directing selected portions of said received programming to a broadcast transmission means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means.</p>

<u>wherein said method delivers said video graphic presentation.</u>	
--	--

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 5,109,414, Claim 7
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</u></p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</u></p> <p><u>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>7. In a signal processing system,</p> <p>a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distributor means and for directing selected portions of said received programming to a broadcast transmission means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means.</p>

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter

station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 5,109,414, Claim 7
<p>177. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p><u>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</u></p> <p><u>delivering said received first completed full-screen video graphic image to a transmitter;</u></p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>transferring said one or more instruct signals to said transmitter; and</u></p> <p><u>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>7. In a signal processing system,</p> <p>a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distributor means and for directing selected portions of said received programming to a broadcast transmission means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means.</p>

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 5,109,414, Claim 7
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</u> <u>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal;</u> <u>passing said at least a first discrete signal to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>7. In a signal processing system, a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distributor means and for directing selected portions of said received programming to a broadcast transmission means, a control signal detector means for detecting control signals respecting said programming and transferring said control signals to storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus.

Application Claim 56	U.S. Pat. No. 5,109,414, Claim 8
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u> <u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u> <u>communicating one of said at least said first request and a second request to a remote data source;</u> <u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u> <u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u> <u>and</u> <u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>8. In a signal processing system, a receiver/distribution means for receiving data from a plurality of data sources and for directing said data to a matrix switch means and a control signal detector means, a matrix switch means for receiving said data from said receiver/distributor means and for directing selected portions of said received data to a processor means, a control signal detector means for detecting switch control signals respecting said data and transferring said switch control signals to a storage/transfer means, said switch control signal detector means being configured to detect said switch control signals in a predetermined frequency range or at a predetermined location within said data as received from said data sources, a storage/transfer means for receiving and storing said switch control signals and for transferring at least a portion of said switch control signals for further processing, and a processor means for receiving and processing said switch control signals, controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 5,109,414, Claim 8
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u> <u>receiving at one of said first transmitter station and a second transmitter station said downloadable</u></p>	<p>8. In a signal processing system, a receiver/distribution means for receiving data from a plurality of data sources and for directing said data to a matrix switch means and a control signal detector means, a matrix switch means for receiving said data from said receiver/distributor means and for directing selected portions of said received data to a processor means, a control signal detector means for detecting switch control signals respecting said data and transferring said switch control signals to a storage/transfer means, said switch control signal detector means being configured to detect said switch control signals in a predetermined frequency range or at a predetermined location within said data as received from said data sources,</p>

<p><u>processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image</u>, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</p> <p>transferring said at least one control signal to said transmitter; and</p> <p>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	<p>a storage/transfer means for receiving and storing said switch control signals and for transferring at least a portion of said switch control signals for further processing, and</p> <p>a processor means for receiving and processing said switch control signals, controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer.</p>
---	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 5,109,414, Claim 8
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</u></p> <p><u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u></p> <p>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</p>	<p>8. In a signal processing system,</p> <p>a receiver/distribution means for receiving data from a plurality of data sources and for directing said data to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said data from said receiver/distributor means and for directing selected portions of said received data to a processor means,</p> <p>a control signal detector means for detecting switch control signals respecting said data and transferring said switch control signals to a storage/transfer means, said switch control signal detector means being configured to detect said switch control signals in a predetermined frequency range or at a predetermined location within said data as received from said data sources,</p> <p>a storage/transfer means for receiving and storing said switch control signals and for transferring at least a portion of said switch control signals for further processing, and</p> <p>a processor means for receiving and processing said switch control signals, controlling the directing</p>

transmitting said at least one control signal from said origination transmitter before a specific time.	functions of said matrix switch means and the transfer functions of said storage/transfer.
---	--

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 5,109,414, Claim 8
<p>84. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</u> <u>receiving video at a transmitter station;</u> <u>delivering said video to a transmitter;</u> <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and <u>transmitting said video and said first discrete signal to said at least one receiver station.</u></p>	<p>8. In a signal processing system, a receiver/distribution means for receiving data from a plurality of data sources and for directing said data to a matrix switch means and a control signal detector means, a matrix switch means for receiving said data from said receiver/distributor means and for directing selected portions of said received data to a processor means, a control signal detector means for detecting switch control signals respecting said data and transferring said switch control signals to a storage/transfer means, said switch control signal detector means being configured to detect said switch control signals in a predetermined frequency range or at a predetermined location within said data as received from said data sources, a storage/transfer means for receiving and storing said switch control signals and for transferring at least a portion of said switch control signals for further processing, and a processor means for receiving and processing said switch control signals, controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer.</p>

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 5,109,414, Claim 8
<p>93. <u>A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said</u></p>	<p>8. In a signal processing system, a receiver/distribution means for receiving data from a plurality of data sources and for directing said data to a matrix switch means and a control signal</p>

<p>method comprising the steps of:</p> <p>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal;</p> <p>detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission;</p> <p>passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor;</p> <p><u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>detector means,</p> <p>a matrix switch means for receiving said data from said receiver/distributor means and for directing selected portions of said received data to a processor means,</p> <p>a control signal detector means for detecting switch control signals respecting said data and transferring said switch control signals to a storage/transfer means, said switch control signal detector means being configured to detect said switch control signals in a predetermined frequency range or at a predetermined location within said data as received from said data sources,</p> <p>a storage/transfer means for receiving and storing said switch control signals and for transferring at least a portion of said switch control signals for further processing, and</p> <p>a processor means for receiving and processing said switch control signals, controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer.</p>
---	--

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 5,109,414, Claim 8
<p>110. A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</p> <p><u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information</u></p>	<p>8. In a signal processing system,</p> <p>a receiver/distribution means for receiving data from a plurality of data sources and for directing said data to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said data from said receiver/distributor means and for directing selected portions of said received data to a processor means,</p> <p>a control signal detector means for detecting switch control signals respecting said data and transferring said switch control signals to a storage/transfer means, said switch control signal detector means</p>

<p><u>contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u> transferring said at least said first discrete signal to at least one transmitter; receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>being configured to detect said switch control signals in a predetermined frequency range or at a predetermined location within said data as received from said data sources, a storage/transfer means for receiving and storing said switch control signals and for transferring at least a portion of said switch control signals for further processing, and a processor means for receiving and processing said switch control signals, controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer.</p>
--	---

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 5,109,414, Claim 8
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u> <u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u> receiving at least one control signal which at said</p>	<p>8. In a signal processing system, a receiver/distribution means for receiving data from a plurality of data sources and for directing said data to a matrix switch means and a control signal detector means, a matrix switch means for receiving said data from said receiver/distributor means and for directing selected portions of said received data to a processor means, a control signal detector means for detecting switch control signals respecting said data and transferring said switch control signals to a storage/transfer means, said switch control signal detector means being configured to detect said switch control signals in a predetermined frequency range or at a predetermined location within said data as received from said data sources, a storage/transfer means for receiving and storing said switch control signals and for transferring at least a portion of said switch control signals for further processing, and a processor means for receiving and processing said switch control signals, controlling the directing functions of said matrix switch means and the transfer</p>

remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction; transferring said at least one control signal to said at least one origination transmitter before a specific time; and transmitting from said at least one origination transmitter said first discrete signal and said at least one control signal.	functions of said storage/transfer.
--	-------------------------------------

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 5,109,414, Claim 8
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u></p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p>transferring said at least one instruct signal to at least one transmitter;</p> <p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of</u></p>	<p>8. In a signal processing system,</p> <p>a receiver/distribution means for receiving data from a plurality of data sources and for directing said data to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said data from said receiver/distributor means and for directing selected portions of said received data to a processor means,</p> <p>a control signal detector means for detecting switch control signals respecting said data and transferring said switch control signals to a storage/transfer means, said switch control signal detector means being configured to detect said switch control signals in a predetermined frequency range or at a predetermined location within said data as received from said data sources,</p> <p>a storage/transfer means for receiving and storing said switch control signals and for transferring at least a portion of said switch control signals for further processing, and</p> <p>a processor means for receiving and processing said switch control signals, controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer.</p>

<p><u>receiver stations</u>, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and</p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	
--	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 5,109,414, Claim 8
<p>142. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction;</u> and</p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>8. In a signal processing system,</p> <p>a receiver/distribution means for receiving data from a plurality of data sources and for directing said data to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said data from said receiver/distributor means and for directing selected portions of said received data to a processor means,</p> <p>a control signal detector means for detecting switch control signals respecting said data and transferring said switch control signals to a storage/transfer means, said switch control signal detector means being configured to detect said switch control signals in a predetermined frequency range or at a predetermined location within said data as received from said data sources,</p> <p>a storage/transfer means for receiving and storing said switch control signals and for transferring at least a portion of said switch control signals for further processing, and</p> <p>a processor means for receiving and processing said switch control signals, controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 5,109,414, Claim 8
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u></p> <ul style="list-style-type: none"> receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to <u>processor instructions comprising said organized information,</u> based on said step of organizing; generating a signal based on said processor instructions; and <u>outputting at least a portion of said video presentation based on said generated signal.</u> 	<p>8. In a signal processing system,</p> <ul style="list-style-type: none"> a receiver/distribution means for receiving data from a plurality of data sources and for directing said data to a matrix switch means and a control signal detector means, a matrix switch means for receiving said data from said receiver/distributor means and for directing selected portions of said received data to a processor means, a control signal detector means for detecting switch control signals respecting said data and transferring said switch control signals to a storage/transfer means, said switch control signal detector means being configured to detect said switch control signals in a predetermined frequency range or at a predetermined location within said data as received from said data sources, a storage/transfer means for receiving and storing said switch control signals and for transferring at least a portion of said switch control signals for further processing, and a processor means for receiving and processing said switch control signals, controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer.

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 5,109,414, Claim 8
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process <u>downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation</u> and have a target processor to process data, <u>said video presentation comprised of said local image of said video</u></u></p>	<p>8. In a signal processing system,</p> <ul style="list-style-type: none"> a receiver/distribution means for receiving data from a plurality of data sources and for directing said data to a matrix switch means and a control signal detector means, a matrix switch means for receiving said data from said receiver/distributor means and for directing selected portions of said received data to a processor means, a control signal detector means for detecting switch control signals respecting said data and transferring

<p><u>presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</u></p> <p>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p><u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>said switch control signals to a storage/transfer means, said switch control signal detector means being configured to detect said switch control signals in a predetermined frequency range or at a predetermined location within said data as received from said data sources,</p> <p>a storage/transfer means for receiving and storing said switch control signals and for transferring at least a portion of said switch control signals for further processing, and</p> <p>a processor means for receiving and processing said switch control signals, controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer.</p>
---	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 5,109,414, Claim 8
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</u></p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p>	<p>8. In a signal processing system,</p> <p>a receiver/distribution means for receiving data from a plurality of data sources and for directing said data to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said data from said receiver/distributor means and for directing selected portions of said received data to a processor means,</p> <p>a control signal detector means for detecting switch control signals respecting said data and transferring said switch control signals to a storage/transfer means, said switch control signal detector means being configured to detect said switch control signals in a predetermined frequency range or at a predetermined location within said data as received</p>

<p>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</p> <p>transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>from said data sources,</p> <p>a storage/transfer means for receiving and storing said switch control signals and for transferring at least a portion of said switch control signals for further processing, and</p> <p>a processor means for receiving and processing said switch control signals, controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer.</p>
---	---

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 5,109,414, Claim 8
<p>162. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of discrete signals, said method comprising the steps of:</u></p> <p><u>receiving a video image at a transmitter station;</u></p> <p><u>delivering said video image to a transmitter;</u></p> <p><u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u></p> <p>transferring said at least said first of said plurality of discrete signals to said transmitter; and</p> <p>transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>8. In a signal processing system,</p> <p>a receiver/distribution means for receiving data from a plurality of data sources and for directing said data to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said data from said receiver/distributor means and for directing selected portions of said received data to a processor means,</p> <p>a control signal detector means for detecting switch control signals respecting said data and transferring said switch control signals to a storage/transfer means, said switch control signal detector means being configured to detect said switch control signals in a predetermined frequency range or at a predetermined location within said data as received from said data sources,</p> <p>a storage/transfer means for receiving and storing said switch control signals and for transferring at least a portion of said switch control signals for further processing, and</p> <p>a processor means for receiving and processing said switch control signals, controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus.

Application Claim 167	U.S. Pat. No. 5,109,414, Claim 8
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</u> <u>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal of said downloadable code;</u> <u>passing said at least a first discrete signal of said downloadable code to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>8. In a signal processing system, a receiver/distribution means for receiving data from a plurality of data sources and for directing said data to a matrix switch means and a control signal detector means, a matrix switch means for receiving said data from said receiver/distributor means and for directing selected portions of said received data to a processor means, a control signal detector means for detecting switch control signals respecting said data and transferring said switch control signals to a storage/transfer means, said switch control signal detector means being configured to detect said switch control signals in a predetermined frequency range or at a predetermined location within said data as received from said data sources, a storage/transfer means for receiving and storing said switch control signals and for transferring at least a portion of said switch control signals for further processing, and a processor means for receiving and processing said switch control signals, controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer.</p>

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 5,109,414, Claim 8
<p>171. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:</u></p> <p style="padding-left: 2em;"><u>receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</u></p> <p style="padding-left: 2em;"><u>transferring said at least one discrete signal to a transmitter;</u></p> <p style="padding-left: 2em;"><u>receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;</u></p> <p style="padding-left: 2em;"><u>transferring said one or more control signals to said transmitter; and</u></p> <p style="padding-left: 2em;"><u>transmitting a transmission comprising said at least one discrete signal and said one or more control signals,</u></p>	<p>8. In a signal processing system,</p> <p style="padding-left: 2em;">a receiver/distribution means for receiving data from a plurality of data sources and for directing said data to a matrix switch means and a control signal detector means,</p> <p style="padding-left: 2em;">a matrix switch means for receiving said data from said receiver/distributor means and for directing selected portions of said received data to a processor means,</p> <p style="padding-left: 2em;">a control signal detector means for detecting switch control signals respecting said data and transferring said switch control signals to a storage/transfer means, said switch control signal detector means being configured to detect said switch control signals in a predetermined frequency range or at a predetermined location within said data as received from said data sources,</p> <p style="padding-left: 2em;">a storage/transfer means for receiving and storing said switch control signals and for transferring at least a portion of said switch control signals for further processing, and</p> <p style="padding-left: 2em;">a processor means for receiving and processing said switch control signals, controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer.</p>

<u>wherein said method delivers said video graphic presentation.</u>	
--	--

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 5,109,414, Claim 8
<p>175. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</p> <p style="padding-left: 20px;"><u>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</u></p> <p style="padding-left: 20px;"><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p style="padding-left: 20px;"><u>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</u></p> <p style="padding-left: 20px;"><u>transmitting a transmission that contains said at</u></p>	<p>8. In a signal processing system,</p> <p style="padding-left: 20px;">a receiver/distribution means for receiving data from a plurality of data sources and for directing said data to a matrix switch means and a control signal detector means,</p> <p style="padding-left: 20px;">a matrix switch means for receiving said data from said receiver/distributor means and for directing selected portions of said received data to a processor means,</p> <p style="padding-left: 20px;">a control signal detector means for detecting switch control signals respecting said data and transferring said switch control signals to a storage/transfer means, said switch control signal detector means being configured to detect said switch control signals in a predetermined frequency range or at a predetermined location within said data as received from said data sources,</p> <p style="padding-left: 20px;">a storage/transfer means for receiving and storing said switch control signals and for transferring at least a portion of said switch control signals for further processing, and</p> <p style="padding-left: 20px;">a processor means for receiving and processing said switch control signals, controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer.</p>

least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,
wherein said method delivers said video graphic presentation.

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 5,109,414, Claim 8
<p>177. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p><u>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</u></p> <p><u>delivering said received first completed full-screen video graphic image to a transmitter;</u></p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>transferring said one or more instruct signals to said transmitter; and</u></p> <p><u>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one</u></p>	<p>8. In a signal processing system,</p> <p>a receiver/distribution means for receiving data from a plurality of data sources and for directing said data to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said data from said receiver/distributor means and for directing selected portions of said received data to a processor means,</p> <p>a control signal detector means for detecting switch control signals respecting said data and transferring said switch control signals to a storage/transfer means, said switch control signal detector means being configured to detect said switch control signals in a predetermined frequency range or at a predetermined location within said data as received from said data sources,</p> <p>a storage/transfer means for receiving and storing said switch control signals and for transferring at least a portion of said switch control signals for further processing, and</p> <p>a processor means for receiving and processing said switch control signals, controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer.</p>

<u>receiver station,</u> <u>wherein said method delivers said video graphic presentation.</u>	
--	--

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 5,109,414, Claim 8
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</u> <u>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal;</u> <u>passing said at least a first discrete signal to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>8. In a signal processing system, a receiver/distribution means for receiving data from a plurality of data sources and for directing said data to a matrix switch means and a control signal detector means, a matrix switch means for receiving said data from said receiver/distributor means and for directing selected portions of said received data to a processor means, a control signal detector means for detecting switch control signals respecting said data and transferring said switch control signals to a storage/transfer means, said switch control signal detector means being configured to detect said switch control signals in a predetermined frequency range or at a predetermined location within said data as received from said data sources, a storage/transfer means for receiving and storing said switch control signals and for transferring at least a portion of said switch control signals for further processing, and a processor means for receiving and processing said switch control signals, controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus.

Application Claim 56	U.S. Pat. No. 5,109,414, Claim 9
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p>and</p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>9. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a plurality of program sources and directing said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distribution means and for directing selected portions of said received programming to a recording device operatively connected to a multichannel television distribution means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at predetermined locations within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or on local command.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 5,109,414, Claim 9
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable</u></p>	<p>9. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a plurality of program sources and directing said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distribution means and for directing selected portions of said received programming to a recording device operatively connected to a multichannel television distribution means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at predetermined locations within said programming,</p>

<p><u>processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image</u>, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</p> <p>transferring said at least one control signal to said transmitter; and</p> <p>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	<p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or on local command.</p>
---	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 5,109,414, Claim 9
<p>80. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u></p> <p>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</p>	<p>9. In a multichannel television distribution system,</p> <p>a receiver/distributor means for receiving television programming from a plurality of program sources and directing said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distribution means and for directing selected portions of said received programming to a recording device operatively connected to a multichannel television distribution means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at predetermined locations within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer</p>

transmitting said at least one control signal from said origination transmitter before a specific time.	functions of said storage/transfer means in response to said control signals or on local command.
---	---

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 5,109,414, Claim 9
<p>84. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</u></p> <ul style="list-style-type: none"> receiving video at a transmitter station; delivering said video to a transmitter; <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and transmitting said video and said first discrete signal to said at least one receiver station. 	<p>9. In a multichannel television distribution system,</p> <ul style="list-style-type: none"> a receiver/distributor means for receiving television programming from a plurality of program sources and directing said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distribution means and for directing selected portions of said received programming to a recording device operatively connected to a multichannel television distribution means, a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at predetermined locations within said programming, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or on local command.

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 5,109,414, Claim 9
<p>93. <u>A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said</u></p>	<p>9. In a multichannel television distribution system,</p> <ul style="list-style-type: none"> a receiver/distributor means for receiving television programming from a plurality of program sources and directing said programming to a matrix switch

<p>method comprising the steps of:</p> <p>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal;</p> <p>detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission;</p> <p>passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor;</p> <p><u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distribution means and for directing selected portions of said received programming to a recording device operatively connected to a multichannel television distribution means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at predetermined locations within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or on local command.</p>
---	--

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 5,109,414, Claim 9
<p>110. A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</p> <p><u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information</u></p>	<p>9. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a plurality of program sources and directing said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distribution means and for directing selected portions of said received programming to a recording device operatively connected to a multichannel television distribution means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said</p>

<p><u>contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u></p> <p>transferring said at least said first discrete signal to at least one transmitter;</p> <p>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</p> <p>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>control signal detector means being configured to detect said control signals in a predetermined frequency range or at predetermined locations within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or on local command.</p>
--	---

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 5,109,414, Claim 9
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u></p> <p><u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u></p> <p>receiving at least one control signal which at said</p>	<p>9. In a multichannel television distribution system,</p> <p>a receiver/distributor means for receiving television programming from a plurality of program sources and directing said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distribution means and for directing selected portions of said received programming to a recording device operatively connected to a multichannel television distribution means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at predetermined locations within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means in response</p>

remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction; transferring said at least one control signal to said at least one origination transmitter before a specific time; and transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.	to said control signals or on local command.
--	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 5,109,414, Claim 9
<p>123. <u>A method of delivering a video presentation</u> at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p>transferring said at least one instruct signal to at least one transmitter;</p> <p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of</u></p>	<p>9. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a plurality of program sources and directing said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distribution means and for directing selected portions of said received programming to a recording device operatively connected to a multichannel television distribution means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at predetermined locations within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or on local command.</p>

<p><u>receiver stations</u>, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and</p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	
--	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 5,109,414, Claim 9
<p>142. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction;</u> and</p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>9. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a plurality of program sources and directing said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distribution means and for directing selected portions of said received programming to a recording device operatively connected to a multichannel television distribution means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at predetermined locations within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or on local command.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 5,109,414, Claim 9
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u> receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to <u>processor instructions comprising said organized information,</u> based on said step of organizing; generating a signal based on said processor instructions; and outputting at least a portion of said video presentation based on said generated signal.</p>	<p>9. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a plurality of program sources and directing said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distribution means and for directing selected portions of said received programming to a recording device operatively connected to a multichannel television distribution means, a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at predetermined locations within said programming, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or on local command.</p>

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 5,109,414, Claim 9
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video</u></p>	<p>9. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a plurality of program sources and directing said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distribution means and for directing selected portions of said received programming to a recording device operatively connected to a multichannel television distribution means, a control signal detector means for detecting control</p>

<p><u>presentation and a video image which is received at said at least one receiver station from a first remote transmitter station</u>, said method comprising the steps of:</p> <p>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p><u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at predetermined locations within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or on local command.</p>
---	---

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 5,109,414, Claim 9
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p>	<p>9. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a plurality of program sources and directing said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distribution means and for directing selected portions of said received programming to a recording device operatively connected to a multichannel television distribution means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at predetermined locations within</p>

<p>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</p> <p>transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or on local command.</p>
---	---

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 5,109,414, Claim 9
<p>162. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of discrete signals, said method comprising the steps of:</u></p> <p>receiving a video image at a transmitter station;</p> <p>delivering said video image to a transmitter;</p> <p><u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u></p> <p>transferring said at least said first of said plurality of discrete signals to said transmitter; and</p> <p>transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>9. In a multichannel television distribution system,</p> <p>a receiver/distributor means for receiving television programming from a plurality of program sources and directing said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distribution means and for directing selected portions of said received programming to a recording device operatively connected to a multichannel television distribution means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at predetermined locations within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or on local command.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus.

Application Claim 167	U.S. Pat. No. 5,109,414, Claim 9
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u></p> <p>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</p> <p>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal of said downloadable code;</p> <p>passing said at least a first discrete signal of said downloadable code to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u></p> <p><u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u></p> <p>wherein said method delivers said video graphic presentation.</p>	<p>9. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a plurality of program sources and directing said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distribution means and for directing selected portions of said received programming to a recording device operatively connected to a multichannel television distribution means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at predetermined locations within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or on local command.</p>

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 5,109,414, Claim 9
<p>171. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:</u></p> <p><u>receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</u></p> <p><u>transferring said at least one discrete signal to a transmitter;</u></p> <p><u>receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;</u></p> <p><u>transferring said one or more control signals to said transmitter; and</u></p> <p><u>transmitting a transmission comprising said at least one discrete signal and said one or more control signals,</u></p>	<p>9. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a plurality of program sources and directing said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distribution means and for directing selected portions of said received programming to a recording device operatively connected to a multichannel television distribution means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at predetermined locations within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or on local command.</p>

<p>wherein said method delivers said video graphic presentation.</p>	
--	--

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 5,109,414, Claim 9
<p>175. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</p> <p style="padding-left: 20px;">receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</p> <p style="padding-left: 20px;"><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p style="padding-left: 20px;">receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</p> <p style="padding-left: 20px;">transmitting a transmission that contains said at</p>	<p>9. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a plurality of program sources and directing said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distribution means and for directing selected portions of said received programming to a recording device operatively connected to a multichannel television distribution means,</p> <p style="padding-left: 20px;">a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at predetermined locations within said programming,</p> <p style="padding-left: 20px;">a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p style="padding-left: 20px;">a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or on local command.</p>

<p>least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time, wherein said method delivers said video graphic presentation.</p>	
---	--

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 5,109,414, Claim 9
<p>177. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p style="padding-left: 20px;">receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p style="padding-left: 20px;">delivering said received first completed full-screen video graphic image to a transmitter;</p> <p style="padding-left: 20px;"><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p style="padding-left: 20px;">transferring said one or more instruct signals to said transmitter; and</p> <p style="padding-left: 20px;">transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one</p>	<p>9. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a plurality of program sources and directing said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distribution means and for directing selected portions of said received programming to a recording device operatively connected to a multichannel television distribution means,</p> <p style="padding-left: 20px;">a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at predetermined locations within said programming,</p> <p style="padding-left: 20px;">a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p style="padding-left: 20px;">a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or on local command.</p>

receiver station, wherein said method delivers said video graphic presentation.	
--	--

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 5,109,414, Claim 9
<p>179. <u>A method of outputting a video graphic presentation</u> at a receiver station including:</p> <p>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</p> <p>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal;</p> <p>passing said at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u></p> <p><u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u></p> <p>wherein said method delivers said video graphic presentation.</p>	<p>9. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a plurality of program sources and directing said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distribution means and for directing selected portions of said received programming to a recording device operatively connected to a multichannel television distribution means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at predetermined locations within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or on local command.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus.

Application Claim 56	U.S. Pat. No. 5,109,414, Claim 10
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p><u>and</u></p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>10. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a plurality of program sources and outputting said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distribution means and for directing selected portions of said received programming to a multichannel television distribution means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at predetermined locations within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or on local command.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 5,109,414, Claim 10
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable</u></p>	<p>10. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a plurality of program sources and outputting said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distribution means and for directing selected portions of said received programming to a multichannel television distribution means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at predetermined locations within said programming,</p>

<p><u>processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image</u>, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</p> <p>transferring said at least one control signal to said transmitter; and</p> <p>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	<p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or on local command.</p>
---	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 5,109,414, Claim 10
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u></p> <p>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u></p> <p>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</p>	<p>10. In a multichannel television distribution system,</p> <p>a receiver/distributor means for receiving television programming from a plurality of program sources and outputting said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distribution means and for directing selected portions of said received programming to a multichannel television distribution means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at predetermined locations within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer</p>

transmitting said at least one control signal from said origination transmitter before a specific time.	functions of said storage/transfer means in response to said control signals or on local command.
---	---

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 5,109,414, Claim 10
<p>84. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, <u>wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals</u> and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving video at a transmitter station; delivering said video to a transmitter; <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and transmitting said video and said first discrete signal to said at least one receiver station. 	<p>10. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a plurality of program sources and outputting said programming to a matrix switch means and a control signal detector means,</p> <ul style="list-style-type: none"> a matrix switch means for receiving said programming from said receiver/distribution means and for directing selected portions of said received programming to a multichannel television distribution means, a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at predetermined locations within said programming, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or on local command.

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 5,109,414, Claim 10
<p>93. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said</p>	<p>10. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a plurality of program sources and outputting said programming to a matrix switch</p>

<p>method comprising the steps of:</p> <p>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal;</p> <p>detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission;</p> <p>passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor;</p> <p><u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distribution means and for directing selected portions of said received programming to a multichannel television distribution means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at predetermined locations within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or on local command.</p>
---	---

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 5,109,414, Claim 10
<p>110. <u>A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</u></p> <p><u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information</u></p>	<p>10. In a multichannel television distribution system,</p> <p>a receiver/distributor means for receiving television programming from a plurality of program sources and outputting said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distribution means and for directing selected portions of said received programming to a multichannel television distribution means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said</p>

<p><u>contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u></p> <p>transferring said at least said first discrete signal to at least one transmitter;</p> <p><u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u></p> <p>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>control signal detector means being configured to detect said control signals in a predetermined frequency range or at predetermined locations within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or on local command.</p>
---	---

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 5,109,414, Claim 10
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u></p> <p><u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u></p> <p>receiving at least one control signal which at said</p>	<p>10. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a plurality of program sources and outputting said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distribution means and for directing selected portions of said received programming to a multichannel television distribution means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at predetermined locations within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means in response</p>

remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction; transferring said at least one control signal to said at least one origination transmitter before a specific time; and transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.	to said control signals or on local command.
--	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 5,109,414, Claim 10
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u></p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p>transferring said at least one instruct signal to at least one transmitter;</p> <p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of</u></p>	<p>10. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a plurality of program sources and outputting said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distribution means and for directing selected portions of said received programming to a multichannel television distribution means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at predetermined locations within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or on local command.</p>

<p><u>receiver stations</u>, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and</p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	
--	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 5,109,414, Claim 10
<p>142. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>10. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a plurality of program sources and outputting said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distribution means and for directing selected portions of said received programming to a multichannel television distribution means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at predetermined locations within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or on local command.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 5,109,414, Claim 10
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u> receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to <u>processor instructions comprising said organized information,</u> based on said step of organizing; generating a signal based on said processor instructions; and outputting at least a portion of said video presentation based on said generated signal.</p>	<p>10. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a plurality of program sources and outputting said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distribution means and for directing selected portions of said received programming to a multichannel television distribution means, a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at predetermined locations within said programming, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or on local command.</p>

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 5,109,414, Claim 10
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video</u></p>	<p>10. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a plurality of program sources and outputting said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distribution means and for directing selected portions of said received programming to a multichannel television distribution means, a control signal detector means for detecting control</p>

<p><u>presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</u></p> <p>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p><u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at predetermined locations within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or on local command.</p>
---	---

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 5,109,414, Claim 10
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p>	<p>10. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a plurality of program sources and outputting said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distribution means and for directing selected portions of said received programming to a multichannel television distribution means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at predetermined locations within</p>

<p>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</p> <p>transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or on local command.</p>
---	---

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 5,109,414, Claim 10
<p>162. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals</u>, said method comprising the steps of:</p> <p>receiving a video image at a transmitter station;</p> <p>delivering said video image to a transmitter;</p> <p><u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u></p> <p>transferring said at least said first of said plurality of discrete signals to said transmitter; and</p> <p>transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>10. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a plurality of program sources and outputting said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distribution means and for directing selected portions of said received programming to a multichannel television distribution means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at predetermined locations within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or on local command.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus.

Application Claim 167	U.S. Pat. No. 5,109,414, Claim 10
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u></p> <p>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</p> <p>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal of said downloadable code;</p> <p>passing said at least a first discrete signal of said downloadable code to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u></p> <p><u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u></p> <p>wherein said method delivers said video graphic presentation.</p>	<p>10. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a plurality of program sources and outputting said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distribution means and for directing selected portions of said received programming to a multichannel television distribution means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at predetermined locations within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or on local command.</p>

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 5,109,414, Claim 10
<p>171. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:</u></p> <p><u>receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</u></p> <p><u>transferring said at least one discrete signal to a transmitter;</u></p> <p><u>receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;</u></p> <p><u>transferring said one or more control signals to said transmitter; and</u></p> <p><u>transmitting a transmission comprising said at least one discrete signal and said one or more control signals,</u></p>	<p>10. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a plurality of program sources and outputting said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distribution means and for directing selected portions of said received programming to a multichannel television distribution means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at predetermined locations within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or on local command.</p>

wherein said method delivers said video graphic presentation.	
---	--

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 5,109,414, Claim 10
<p>175. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</p> <p>transmitting a transmission that contains said at</p>	<p>10. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a plurality of program sources and outputting said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distribution means and for directing selected portions of said received programming to a multichannel television distribution means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at predetermined locations within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or on local command.</p>

<p>least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time, wherein said method delivers said video graphic presentation.</p>	
--	--

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 5,109,414, Claim 10
<p>177. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>transferring said one or more instruct signals to said transmitter; and</p> <p>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one</p>	<p>10. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a plurality of program sources and outputting said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distribution means and for directing selected portions of said received programming to a multichannel television distribution means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at predetermined locations within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or on local command.</p>

receiver station, wherein said method delivers said video graphic presentation.	
--	--

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 5,109,414, Claim 10
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u></p> <p>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</p> <p>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal;</p> <p>passing said at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u></p> <p><u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u></p> <p>wherein said method delivers said video graphic presentation.</p>	<p>10. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a plurality of program sources and outputting said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distribution means and for directing selected portions of said received programming to a multichannel television distribution means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at predetermined locations within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or on local command.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus.

Application Claim 56	U.S. Pat. No. 5,109,414, Claim 11
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p>and</p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>11. In a multichannel television distribution system, a plurality of receiver/distribution means for receiving television programming from a plurality of program sources and directing said programming to a matrix switch means and a control signal detector and processor means,</p> <p>a matrix switch means for receiving said programming from said plurality of receiver/distribution means and for directing selected portions of said received programming to a recording device operatively connected to a multichannel television distribution means,</p> <p>a control signal detector and processor means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at specified locations within said programming, said control signal detector and processor means controlling the particular ranges and locations wherein said control signals are detected,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or local command.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 5,109,414, Claim 11
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of</u></p>	<p>11. In a multichannel television distribution system, a plurality of receiver/distribution means for receiving television programming from a plurality of program sources and directing said programming to a matrix switch means and a control signal detector and processor means,</p> <p>a matrix switch means for receiving said programming from said plurality of receiver/distribution means and for directing selected portions of said received programming to a recording device operatively connected to a multichannel television distribution means,</p>

<p><u>completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</u></p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</p> <p>transferring said at least one control signal to said transmitter; and</p> <p>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	<p>a control signal detector and processor means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at specified locations within said programming, said control signal detector and processor means controlling the particular ranges and locations wherein said control signals are detected,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or local command.</p>
---	---

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 5,109,414, Claim 11
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u></p> <p>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u></p>	<p>11. In a multichannel television distribution system, a plurality of receiver/distribution means for receiving television programming from a plurality of program sources and directing said programming to a matrix switch means and a control signal detector and processor means,</p> <p>a matrix switch means for receiving said programming from said plurality of receiver/distribution means and for directing selected portions of said received programming to a recording device operatively connected to a multichannel television distribution means,</p> <p>a control signal detector and processor means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at</p>

<p>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</p> <p>transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>specified locations within said programming, said control signal detector and processor means controlling the particular ranges and locations wherein said control signals are detected,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or local command.</p>
--	---

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 5,109,414, Claim 11
<p>84. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, <u>wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals</u> and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <p>receiving video at a transmitter station;</p> <p>delivering said video to a transmitter;</p> <p><u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u></p> <p>transferring said first discrete signal to said transmitter; and</p> <p>transmitting said video and said first discrete signal to said at least one receiver station.</p>	<p>11. In a multichannel television distribution system, a plurality of receiver/distribution means for receiving television programming from a plurality of program sources and directing said programming to a matrix switch means and a control signal detector and processor means,</p> <p>a matrix switch means for receiving said programming from said plurality of receiver/distribution means and for directing selected portions of said received programming to a recording device operatively connected to a multichannel television distribution means,</p> <p>a control signal detector and processor means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at specified locations within said programming, said control signal detector and processor means controlling the particular ranges and locations wherein said control signals are detected,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or local command.</p>

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 5,109,414, Claim 11
<p>93. <u>A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</u></p> <p>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal;</p> <p>detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission;</p> <p>passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor;</p> <p><u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>11. In a multichannel television distribution system, a plurality of receiver/distribution means for receiving television programming from a plurality of program sources and directing said programming to a matrix switch means and a control signal detector and processor means,</p> <p>a matrix switch means for receiving said programming from said plurality of receiver/distribution means and for directing selected portions of said received programming to a recording device operatively connected to a multichannel television distribution means,</p> <p>a control signal detector and processor means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at specified locations within said programming, said control signal detector and processor means controlling the particular ranges and locations wherein said control signals are detected,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or local command.</p>

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 5,109,414, Claim 11
110. <u>A method of outputting a video presentation</u>	11. In a multichannel television distribution system,

<p>at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</p> <p><u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u></p> <p>transferring said at least said first discrete signal to at least one transmitter;</p> <p><u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u></p> <p>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>a plurality of receiver/distribution means for receiving television programming from a plurality of program sources and directing said programming to a matrix switch means and a control signal detector and processor means,</p> <p>a matrix switch means for receiving said programming from said plurality of receiver/distribution means and for directing selected portions of said received programming to a recording device operatively connected to a multichannel television distribution means,</p> <p>a control signal detector and processor means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at specified locations within said programming, said control signal detector and processor means controlling the particular ranges and locations wherein said control signals are detected,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or local command.</p>
---	--

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 5,109,414, Claim 11
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u></p>	<p>11. In a multichannel television distribution system, a plurality of receiver/distribution means for receiving television programming from a plurality of program sources and directing said programming to a matrix switch means and a control signal detector and processor means,</p> <p>a matrix switch means for receiving said programming from said plurality of receiver/distribution means and for directing selected portions of said received programming to a recording device operatively connected to a multichannel television distribution means,</p>

<p><u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u></p> <p>receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</p> <p>transferring said at least one control signal to said at least one origination transmitter before a specific time; and</p> <p>transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	<p>a control signal detector and processor means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at specified locations within said programming, said control signal detector and processor means controlling the particular ranges and locations wherein said control signals are detected,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or local command.</p>
---	---

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 5,109,414, Claim 11
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u></p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p>transferring said at least one instruct signal to at</p>	<p>11. In a multichannel television distribution system, a plurality of receiver/distribution means for receiving television programming from a plurality of program sources and directing said programming to a matrix switch means and a control signal detector and processor means,</p> <p>a matrix switch means for receiving said programming from said plurality of receiver/distribution means and for directing selected portions of said received programming to a recording device operatively connected to a multichannel television distribution means,</p> <p>a control signal detector and processor means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at specified locations within said programming, said control signal detector and processor means controlling the particular ranges and locations</p>

<p>least one transmitter; <u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations,</u> wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	<p>wherein said control signals are detected, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or local command.</p>
---	---

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 5,109,414, Claim 11
<p>142. <u>A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</u> receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal; detecting said at least a first discrete signal and said at least one control signal in said information transmission; passing said detected at least a first discrete signal to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized</u></p>	<p>11. In a multichannel television distribution system, a plurality of receiver/distribution means for receiving television programming from a plurality of program sources and directing said programming to a matrix switch means and a control signal detector and processor means, a matrix switch means for receiving said programming from said plurality of receiver/distribution means and for directing selected portions of said received programming to a recording device operatively connected to a multichannel television distribution means, a control signal detector and processor means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at specified locations within said programming, said</p>

<p><u>information from said step of organizing;</u> responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; <u>generating only a portion of said video image based on said step of responding to said at least one processor instruction;</u> and <u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>control signal detector and processor means controlling the particular ranges and locations wherein said control signals are detected, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or local command.</p>
--	---

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 5,109,414, Claim 11
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u> receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to <u>processor instructions comprising said organized information,</u> based on said step of organizing; generating a signal based on said processor instructions; and outputting at least a portion of said video presentation based on said generated signal.</p>	<p>11. In a multichannel television distribution system, a plurality of receiver/distribution means for receiving television programming from a plurality of program sources and directing said programming to a matrix switch means and a control signal detector and processor means, a matrix switch means for receiving said programming from said plurality of receiver/distribution means and for directing selected portions of said received programming to a recording device operatively connected to a multichannel television distribution means, a control signal detector and processor means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at specified locations within said programming, said control signal detector and processor means controlling the particular ranges and locations wherein said control signals are detected, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or local command.</p>

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 5,109,414, Claim 11
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</u></p> <p style="padding-left: 40px;">receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</p> <p style="padding-left: 40px;">transferring said downloadable processor instructions to a transmitter;</p> <p style="padding-left: 40px;"><u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p style="padding-left: 40px;">transferring said one or more control signals to said transmitter; and</p> <p style="padding-left: 40px;">transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>11. In a multichannel television distribution system, a plurality of receiver/distribution means for receiving television programming from a plurality of program sources and directing said programming to a matrix switch means and a control signal detector and processor means,</p> <p style="padding-left: 40px;">a matrix switch means for receiving said programming from said plurality of receiver/distribution means and for directing selected portions of said received programming to a recording device operatively connected to a multichannel television distribution means,</p> <p style="padding-left: 40px;">a control signal detector and processor means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at specified locations within said programming, said control signal detector and processor means controlling the particular ranges and locations wherein said control signals are detected,</p> <p style="padding-left: 40px;">a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p style="padding-left: 40px;">a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or local command.</p>

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 5,109,414, Claim 11
<p>157. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</p> <p>transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>11. In a multichannel television distribution system, a plurality of receiver/distribution means for receiving television programming from a plurality of program sources and directing said programming to a matrix switch means and a control signal detector and processor means,</p> <p>a matrix switch means for receiving said programming from said plurality of receiver/distribution means and for directing selected portions of said received programming to a recording device operatively connected to a multichannel television distribution means,</p> <p>a control signal detector and processor means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at specified locations within said programming, said control signal detector and processor means controlling the particular ranges and locations wherein said control signals are detected,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or local command.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 5,109,414, Claim 11
<p>162. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals</u>, said method comprising the steps of:</p>	<p>11. In a multichannel television distribution system, a plurality of receiver/distribution means for receiving television programming from a plurality of program sources and directing said programming to a matrix switch means and a control signal detector and processor means,</p> <p>a matrix switch means for receiving said programming from said plurality of receiver/distribution means and for directing selected</p>

<p>receiving a video image at a transmitter station; delivering said video image to a transmitter; <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> transferring said at least said first of said plurality of discrete signals to said transmitter; and transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>portions of said received programming to a recording device operatively connected to a multichannel television distribution means, a control signal detector and processor means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at specified locations within said programming, said control signal detector and processor means controlling the particular ranges and locations wherein said control signals are detected, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or local command.</p>
--	---

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus.

Application Claim 167	U.S. Pat. No. 5,109,414, Claim 11
<p>167. <u>A method of outputting a video graphic presentation</u> at a receiver station including: receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image; passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen; displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen; detecting said at least a first discrete signal of said downloadable code; passing said at least a first discrete signal of said downloadable code to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal</u></p>	<p>11. In a multichannel television distribution system, a plurality of receiver/distribution means for receiving television programming from a plurality of program sources and directing said programming to a matrix switch means and a control signal detector and processor means, a matrix switch means for receiving said programming from said plurality of receiver/distribution means and for directing selected portions of said received programming to a recording device operatively connected to a multichannel television distribution means, a control signal detector and processor means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at specified locations within said programming, said control signal detector and processor means controlling the particular ranges and locations wherein said control signals are detected,</p>

<p><u>based on at least one control signal;</u> responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> passing, to said video monitor based on said step of responding to at least one processor instruction, <u>only a portion of a second completed full-screen video graphic image;</u> and displaying, at said video monitor, <u>said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> wherein said method delivers said video graphic presentation.</p>	<p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or local command.</p>
--	---

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 5,109,414, Claim 11
<p>171. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:</u></p>	<p>11. In a multichannel television distribution system, a plurality of receiver/distribution means for receiving television programming from a plurality of program sources and directing said programming to a matrix switch means and a control signal detector and processor means, a matrix switch means for receiving said programming from said plurality of receiver/distribution means and for directing selected portions of said received programming to a recording device operatively connected to a multichannel television distribution means, a control signal detector and processor means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at specified locations within said programming, said control signal detector and processor means controlling the particular ranges and locations wherein said control signals are detected, a storage/transfer means for receiving and storing said control signals and for transferring at least a</p>

<p><u>receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</u> transferring said at least one discrete signal to a transmitter; receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image; transferring said one or more control signals to said transmitter; and transmitting a transmission comprising said at least one discrete signal and said one or more control signals, wherein said method delivers said video graphic presentation.</p>	<p>portion of said control signals for further processing, and a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or local command.</p>
--	---

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 5,109,414, Claim 11
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u> receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</p>	<p>11. In a multichannel television distribution system, a plurality of receiver/distribution means for receiving television programming from a plurality of program sources and directing said programming to a matrix switch means and a control signal detector and processor means, a matrix switch means for receiving said programming from said plurality of receiver/distribution means and for directing selected portions of said received programming to a recording device operatively connected to a multichannel television distribution means, a control signal detector and processor means for detecting control signals respecting said programming and transferring said control signals to a</p>

<p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</p> <p>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>storage/transfer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at specified locations within said programming, said control signal detector and processor means controlling the particular ranges and locations wherein said control signals are detected,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or local command.</p>
--	--

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 5,109,414, Claim 11
<p>177. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire</p>	<p>11. In a multichannel television distribution system, a plurality of receiver/distribution means for receiving television programming from a plurality of program sources and directing said programming to a matrix switch means and a control signal detector and processor means,</p> <p>a matrix switch means for receiving said programming from said plurality of receiver/distribution means and for directing selected portions of said received programming to a recording device operatively connected to a multichannel</p>

<p>surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>transferring said one or more instruct signals to said transmitter; and</p> <p>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>television distribution means,</p> <p>a control signal detector and processor means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at specified locations within said programming, said control signal detector and processor means controlling the particular ranges and locations wherein said control signals are detected,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or local command.</p>
--	---

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 5,109,414, Claim 11
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u></p> <p>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</p> <p>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p>	<p>11. In a multichannel television distribution system, a plurality of receiver/distribution means for receiving television programming from a plurality of program sources and directing said programming to a matrix switch means and a control signal detector and processor means,</p> <p>a matrix switch means for receiving said programming from said plurality of receiver/distribution means and for directing selected portions of said received programming to a recording device operatively connected to a multichannel television distribution means,</p> <p>a control signal detector and processor means for detecting control signals respecting said programming</p>

<p>detecting said at least a first discrete signal; passing said at least a first discrete signal to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image;</u> and <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> wherein said method delivers said video graphic presentation.</p>	<p>and transferring said control signals to a storage/transfer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at specified locations within said programming, said control signal detector and processor means controlling the particular ranges and locations wherein said control signals are detected, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or local command.</p>
---	---

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus.

Application Claim 56	U.S. Pat. No. 5,109,414, Claim 12
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p><u>and</u></p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>12. In a multichannel television distribution system, a plurality of receiver/distribution means for receiving television programming from a plurality of program sources and outputting said programming to a matrix switch means and a control signal detector and processor means,</p> <p>a matrix switch means for receiving said programming from said plurality of receiver/distribution means and for outputting selected portions of said received programming to a multichannel television distribution means,</p> <p>a control signal detector and processor means for detecting control signal respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at specified locations within said programming, said control signal detector and processor means controlling the particular ranges and locations wherein said control signals are detected,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the output functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or local command.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 5,109,414, Claim 12
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and</u></p>	<p>12. In a multichannel television distribution system, a plurality of receiver/distribution means for receiving television programming from a plurality of program sources and outputting said programming to a matrix switch means and a control signal detector and processor means,</p> <p>a matrix switch means for receiving said programming from said plurality of receiver/distribution means and for outputting selected portions of said received programming to a multichannel television distribution means,</p> <p>a control signal detector and processor means for detecting control signal respecting said programming</p>

<p><u>displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</u></p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</p> <p>transferring said at least one control signal to said transmitter; and</p> <p>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	<p>and transferring said control signals to a storage/transfer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at specified locations within said programming, said control signal detector and processor means controlling the particular ranges and locations wherein said control signals are detected,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the output functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or local command.</p>
--	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 5,109,414, Claim 12
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u></p> <p>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u></p> <p>receiving, at said origination transmitter station, at</p>	<p>12. In a multichannel television distribution system,</p> <p>a plurality of receiver/distribution means for receiving television programming from a plurality of program sources and outputting said programming to a matrix switch means and a control signal detector and processor means,</p> <p>a matrix switch means for receiving said programming from said plurality of receiver/distribution means and for outputting selected portions of said received programming to a multichannel television distribution means,</p> <p>a control signal detector and processor means for detecting control signal respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at specified locations within said programming, said control signal detector and processor means</p>

<p>least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</p> <p>transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>controlling the particular ranges and locations wherein said control signals are detected,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the output functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or local command.</p>
---	--

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 5,109,414, Claim 12
<p>84. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, <u>wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals</u> and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <p>receiving video at a transmitter station;</p> <p>delivering said video to a transmitter;</p> <p><u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u></p> <p>transferring said first discrete signal to said transmitter; and</p> <p>transmitting said video and said first discrete signal to said at least one receiver station.</p>	<p>12. In a multichannel television distribution system,</p> <p>a plurality of receiver/distribution means for receiving television programming from a plurality of program sources and outputting said programming to a matrix switch means and a control signal detector and processor means,</p> <p>a matrix switch means for receiving said programming from said plurality of receiver/distribution means and for outputting selected portions of said received programming to a multichannel television distribution means,</p> <p>a control signal detector and processor means for detecting control signal respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at specified locations within said programming, said control signal detector and processor means controlling the particular ranges and locations wherein said control signals are detected,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the output functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or local command.</p>

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 5,109,414, Claim 12
<p>93. <u>A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</u></p> <p>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal;</p> <p>detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission;</p> <p>passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor;</p> <p><u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>12. In a multichannel television distribution system, a plurality of receiver/distribution means for receiving television programming from a plurality of program sources and outputting said programming to a matrix switch means and a control signal detector and processor means,</p> <p>a matrix switch means for receiving said programming from said plurality of receiver/distribution means and for outputting selected portions of said received programming to a multichannel television distribution means,</p> <p>a control signal detector and processor means for detecting control signal respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at specified locations within said programming, said control signal detector and processor means controlling the particular ranges and locations wherein said control signals are detected,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the output functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or local command.</p>

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 5,109,414, Claim 12
<p>110. <u>A method of outputting a video presentation at at least one of a plurality of receiver stations each of</u></p>	<p>12. In a multichannel television distribution system, a plurality of receiver/distribution means for</p>

<p>which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</p> <p><u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u></p> <p>transferring said at least said first discrete signal to at least one transmitter;</p> <p><u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u></p> <p>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>receiving television programming from a plurality of program sources and outputting said programming to a matrix switch means and a control signal detector and processor means,</p> <p>a matrix switch means for receiving said programming from said plurality of receiver/distribution means and for outputting selected portions of said received programming to a multichannel television distribution means,</p> <p>a control signal detector and processor means for detecting control signal respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at specified locations within said programming, said control signal detector and processor means controlling the particular ranges and locations wherein said control signals are detected,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the output functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or local command.</p>
---	---

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 5,109,414, Claim 12
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u></p> <p><u>receiving a first discrete signal at an origination</u></p>	<p>12. In a multichannel television distribution system, a plurality of receiver/distribution means for receiving television programming from a plurality of program sources and outputting said programming to a matrix switch means and a control signal detector and processor means,</p> <p>a matrix switch means for receiving said programming from said plurality of receiver/distribution means and for outputting selected portions of said received programming to a multichannel television distribution means,</p> <p>a control signal detector and processor means for detecting control signal respecting said programming</p>

<p><u>transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u></p> <p>receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</p> <p>transferring said at least one control signal to said at least one origination transmitter before a specific time; and</p> <p>transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	<p>and transferring said control signals to a storage/transfer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at specified locations within said programming, said control signal detector and processor means controlling the particular ranges and locations wherein said control signals are detected,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the output functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or local command.</p>
---	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 5,109,414, Claim 12
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u></p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p>transferring said at least one instruct signal to at least one transmitter;</p>	<p>12. In a multichannel television distribution system, a plurality of receiver/distribution means for receiving television programming from a plurality of program sources and outputting said programming to a matrix switch means and a control signal detector and processor means,</p> <p>a matrix switch means for receiving said programming from said plurality of receiver/distribution means and for outputting selected portions of said received programming to a multichannel television distribution means,</p> <p>a control signal detector and processor means for detecting control signal respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at specified locations within said programming, said control signal detector and processor means controlling the particular ranges and locations wherein said control signals are detected,</p> <p>a storage/transfer means for receiving and storing</p>

<p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and</u></p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	<p>said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the output functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or local command.</p>
---	---

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 5,109,414, Claim 12
<p>142. <u>A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</u></p> <p style="padding-left: 20px;">receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p style="padding-left: 20px;">detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p style="padding-left: 20px;">passing said detected at least a first discrete signal to at least one processor;</p> <p style="padding-left: 20px;"><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p style="padding-left: 20px;">passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p>	<p>12. In a multichannel television distribution system, a plurality of receiver/distribution means for receiving television programming from a plurality of program sources and outputting said programming to a matrix switch means and a control signal detector and processor means,</p> <p style="padding-left: 20px;">a matrix switch means for receiving said programming from said plurality of receiver/distribution means and for outputting selected portions of said received programming to a multichannel television distribution means,</p> <p style="padding-left: 20px;">a control signal detector and processor means for detecting control signal respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at specified locations within said programming, said control signal detector and processor means controlling the particular ranges and locations</p>

<p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; <u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>wherein said control signals are detected, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the output functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or local command.</p>
--	--

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 5,109,414, Claim 12
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u> receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to <u>processor instructions comprising said organized information,</u> based on said step of organizing; generating a signal based on said processor instructions; and outputting at least a portion of said video presentation based on said generated signal.</p>	<p>12. In a multichannel television distribution system, a plurality of receiver/distribution means for receiving television programming from a plurality of program sources and outputting said programming to a matrix switch means and a control signal detector and processor means, a matrix switch means for receiving said programming from said plurality of receiver/distribution means and for outputting selected portions of said received programming to a multichannel television distribution means, a control signal detector and processor means for detecting control signal respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at specified locations within said programming, said control signal detector and processor means controlling the particular ranges and locations wherein said control signals are detected, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the output functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or local command.</p>

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 5,109,414, Claim 12
<p>152. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process <u>downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation</u> and have a target processor to process data, <u>said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station</u>, said method comprising the steps of:</p> <p>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p><u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>12. In a multichannel television distribution system, a plurality of receiver/distribution means for receiving television programming from a plurality of program sources and outputting said programming to a matrix switch means and a control signal detector and processor means,</p> <p>a matrix switch means for receiving said programming from said plurality of receiver/distribution means and for outputting selected portions of said received programming to a multichannel television distribution means,</p> <p>a control signal detector and processor means for detecting control signal respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at specified locations within said programming, said control signal detector and processor means controlling the particular ranges and locations wherein said control signals are detected,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the output functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or local command.</p>

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 5,109,414, Claim 12
157. <u>A method of delivering a video presentation</u>	12. In a multichannel television distribution system,

<p>at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</p> <p>transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>a plurality of receiver/distribution means for receiving television programming from a plurality of program sources and outputting said programming to a matrix switch means and a control signal detector and processor means,</p> <p>a matrix switch means for receiving said programming from said plurality of receiver/distribution means and for outputting selected portions of said received programming to a multichannel television distribution means,</p> <p>a control signal detector and processor means for detecting control signal respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at specified locations within said programming, said control signal detector and processor means controlling the particular ranges and locations wherein said control signals are detected,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the output functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or local command.</p>
---	--

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 5,109,414, Claim 12
<p>162. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals</u>, said method comprising the steps of:</p> <p>receiving a video image at a transmitter station;</p> <p>delivering said video image to a transmitter;</p> <p><u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete</u></p>	<p>12. In a multichannel television distribution system, a plurality of receiver/distribution means for receiving television programming from a plurality of program sources and outputting said programming to a matrix switch means and a control signal detector and processor means,</p> <p>a matrix switch means for receiving said programming from said plurality of receiver/distribution means and for outputting selected portions of said received programming to a multichannel television distribution means,</p> <p>a control signal detector and processor means for detecting control signal respecting said programming and transferring said control signals to a</p>

<p><u>signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> transferring said at least said first of said plurality of discrete signals to said transmitter; and transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>storage/transfer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at specified locations within said programming, said control signal detector and processor means controlling the particular ranges and locations wherein said control signals are detected, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the output functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or local command.</p>
---	---

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus.

Application Claim 167	U.S. Pat. No. 5,109,414, Claim 12
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u> receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image; passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen; displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen; detecting said at least a first discrete signal of said downloadable code; passing said at least a first discrete signal of said downloadable code to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of</u></p>	<p>12. In a multichannel television distribution system, a plurality of receiver/distribution means for receiving television programming from a plurality of program sources and outputting said programming to a matrix switch means and a control signal detector and processor means, a matrix switch means for receiving said programming from said plurality of receiver/distribution means and for outputting selected portions of said received programming to a multichannel television distribution means, a control signal detector and processor means for detecting control signal respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at specified locations within said programming, said control signal detector and processor means controlling the particular ranges and locations wherein said control signals are detected, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the output functions of said matrix switch means and the transfer functions of said storage/transfer means in response</p>

<p><u>responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> wherein said method delivers said video graphic presentation.</p>	<p>to said control signals or local command.</p>
--	--

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 5,109,414, Claim 12
<p>171. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:</u> <u>receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</u> <u>transferring said at least one discrete signal to a</u></p>	<p>12. In a multichannel television distribution system, a plurality of receiver/distribution means for receiving television programming from a plurality of program sources and outputting said programming to a matrix switch means and a control signal detector and processor means, a matrix switch means for receiving said programming from said plurality of receiver/distribution means and for outputting selected portions of said received programming to a multichannel television distribution means, a control signal detector and processor means for detecting control signal respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at specified locations within said programming, said control signal detector and processor means controlling the particular ranges and locations wherein said control signals are detected, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the output functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or local command.</p>

<p>transmitter; <u>receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;</u> transferring said one or more control signals to said transmitter; and transmitting a transmission comprising said at least one discrete signal and said one or more control signals, wherein said method delivers said video graphic presentation.</p>	
--	--

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 5,109,414, Claim 12
<p>175. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a</u></p>	<p>12. In a multichannel television distribution system, a plurality of receiver/distribution means for receiving television programming from a plurality of program sources and outputting said programming to a matrix switch means and a control signal detector and processor means,</p> <p>a matrix switch means for receiving said programming from said plurality of receiver/distribution means and for outputting selected portions of said received programming to a multichannel television distribution means,</p> <p>a control signal detector and processor means for detecting control signal respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at specified locations within said programming, said control signal detector and processor means controlling the particular ranges and locations wherein said control signals are detected,</p>

<p><u>second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</p> <p>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the output functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or local command.</p>
---	--

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 5,109,414, Claim 12
<p>177. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at</u></p>	<p>12. In a multichannel television distribution system, a plurality of receiver/distribution means for receiving television programming from a plurality of program sources and outputting said programming to a matrix switch means and a control signal detector and processor means,</p> <p>a matrix switch means for receiving said programming from said plurality of receiver/distribution means and for outputting selected portions of said received programming to a multichannel television distribution means,</p> <p>a control signal detector and processor means for detecting control signal respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at</p>

<p><u>said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>transferring said one or more instruct signals to said transmitter; and</p> <p>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>specified locations within said programming, said control signal detector and processor means controlling the particular ranges and locations wherein said control signals are detected,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the output functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or local command.</p>
--	--

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 5,109,414, Claim 12
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u></p> <p>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</p> <p>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal;</p> <p>passing said at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal</u></p>	<p>12. In a multichannel television distribution system, a plurality of receiver/distribution means for receiving television programming from a plurality of program sources and outputting said programming to a matrix switch means and a control signal detector and processor means,</p> <p>a matrix switch means for receiving said programming from said plurality of receiver/distribution means and for outputting selected portions of said received programming to a multichannel television distribution means,</p> <p>a control signal detector and processor means for detecting control signal respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at specified locations within said programming, said control signal detector and processor means controlling the particular ranges and locations</p>

<p><u>based on at least one control signal;</u> <u>responding to at least one processor instruction at</u> <u>said receiver station, said at least one processor</u> <u>instruction comprising said organized information</u> <u>from said step of organizing;</u> <u>passing, to said video monitor based on said step of</u> <u>responding to at least one processor instruction, only a</u> <u>portion of a second completed full-screen video</u> <u>graphic image; and</u> <u>displaying said second completed full-screen video</u> <u>graphic image at said video monitor, said displayed</u> <u>second completed full-screen video graphic image</u> <u>filling the entire surface area of said viewing screen</u> <u>and containing said passed only said portion of said</u> <u>second completed full-screen video graphic image</u> <u>and only a portion of said first completed full-screen</u> <u>video graphic image,</u> wherein said method delivers said video graphic presentation.</p>	<p>wherein said control signals are detected, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the output functions of said matrix switch means and the transfer functions of said storage/transfer means in response to said control signals or local command.</p>
--	--

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus.

Application Claim 56	U.S. Pat. No. 5,109,414, Claim 13
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p><u>and</u></p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>13. In a multichannel television distribution system, a receiver/distribution means for receiving television programming from a multichannel television transmission facility and outputting said programming to a matrix switch means and a control signal detector and processor means,</p> <p>a matrix switch means for receiving said programming from said receiver/distribution means and for outputting selected portions of said received programming to a multichannel television distribution means,</p> <p>a control signal detector and processor means for detecting control signals respecting said programming and transferring said control signals to a buffer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at specified locations within said programming, said control signal detector and processor means controlling the particular ranges and locations wherein said control signals are detected,</p> <p>a buffer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the output functions of said matrix switch means and the transfer functions of said buffer means in response to said control signals.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 5,109,414, Claim 13
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image,</u></p>	<p>13. In a multichannel television distribution system, a receiver/distribution means for receiving television programming from a multichannel television transmission facility and outputting said programming to a matrix switch means and a control signal detector and processor means,</p> <p>a matrix switch means for receiving said programming from said receiver/distribution means and for outputting selected portions of said received programming to a multichannel television distribution means,</p> <p>a control signal detector and processor means for detecting control signals respecting said programming and transferring said control signals to a buffer means,</p>

<p>said method comprising the steps of:</p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</u></p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</p> <p>transferring said at least one control signal to said transmitter; and</p> <p>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	<p>said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at specified locations within said programming, said control signal detector and processor means controlling the particular ranges and locations wherein said control signals are detected,</p> <p>a buffer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the output functions of said matrix switch means and the transfer functions of said buffer means in response to said control signals.</p>
---	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 5,109,414, Claim 13
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u></p> <p>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u></p> <p>receiving, at said origination transmitter station, at least one control signal that, at the remote</p>	<p>13. In a multichannel television distribution system, a receiver/distribution means for receiving television programming from a multichannel television transmission facility and outputting said programming to a matrix switch means and a control signal detector and processor means,</p> <p>a matrix switch means for receiving said programming from said receiver/distribution means and for outputting selected portions of said received programming to a multichannel television distribution means,</p> <p>a control signal detector and processor means for detecting control signals respecting said programming and transferring said control signals to a buffer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at specified locations within said programming, said control signal detector and processor means controlling the particular ranges and locations wherein said control signals are</p>

intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and transmitting said at least one control signal from said origination transmitter before a specific time.	detected, a buffer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the output functions of said matrix switch means and the transfer functions of said buffer means in response to said control signals.
---	---

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 5,109,414, Claim 13
<p>84. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, <u>wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals</u> and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <p>receiving video at a transmitter station; delivering said video to a transmitter; <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and transmitting said video and said first discrete signal to said at least one receiver station.</p>	<p>13. In a multichannel television distribution system, a receiver/distribution means for receiving television programming from a multichannel television transmission facility and outputting said programming to a matrix switch means and a control signal detector and processor means, a matrix switch means for receiving said programming from said receiver/distribution means and for outputting selected portions of said received programming to a multichannel television distribution means, a control signal detector and processor means for detecting control signals respecting said programming and transferring said control signals to a buffer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at specified locations within said programming, said control signal detector and processor means controlling the particular ranges and locations wherein said control signals are detected, a buffer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the output functions of said matrix switch means and the transfer functions of said buffer means in response to said control signals.</p>

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 5,109,414, Claim 13
<p>93. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <p>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal;</p> <p>detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission;</p> <p>passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor;</p> <p><u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>13. In a multichannel television distribution system, a receiver/distribution means for receiving television programming from a multichannel television transmission facility and outputting said programming to a matrix switch means and a control signal detector and processor means,</p> <p>a matrix switch means for receiving said programming from said receiver/distribution means and for outputting selected portions of said received programming to a multichannel television distribution means,</p> <p>a control signal detector and processor means for detecting control signals respecting said programming and transferring said control signals to a buffer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at specified locations within said programming, said control signal detector and processor means controlling the particular ranges and locations wherein said control signals are detected,</p> <p>a buffer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the output functions of said matrix switch means and the transfer functions of said buffer means in response to said control signals.</p>

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 5,109,414, Claim 13
<p>110. <u>A method of outputting a video presentation</u> at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method</p>	<p>13. In a multichannel television distribution system, a receiver/distribution means for receiving television programming from a multichannel television transmission facility and outputting said programming to a matrix switch means and a control signal detector and processor means,</p> <p>a matrix switch means for receiving said</p>

<p>comprising the steps of:</p> <p><u>receiving at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u></p> <p>transferring said at least said first discrete signal to at least one transmitter;</p> <p><u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u></p> <p>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>programming from said receiver/distribution means and for outputting selected portions of said received programming to a multichannel television distribution means,</p> <p>a control signal detector and processor means for detecting control signals respecting said programming and transferring said control signals to a buffer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at specified locations within said programming, said control signal detector and processor means controlling the particular ranges and locations wherein said control signals are detected,</p> <p>a buffer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the output functions of said matrix switch means and the transfer functions of said buffer means in response to said control signals.</p>
---	---

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 5,109,414, Claim 13
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u></p> <p><u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and</u></p>	<p>13. In a multichannel television distribution system, a receiver/distribution means for receiving television programming from a multichannel television transmission facility and outputting said programming to a matrix switch means and a control signal detector and processor means,</p> <p>a matrix switch means for receiving said programming from said receiver/distribution means and for outputting selected portions of said received programming to a multichannel television distribution means,</p> <p>a control signal detector and processor means for detecting control signals respecting said programming and transferring said control signals to a buffer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at specified locations within said programming, said control signal detector</p>

<p><u>wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u></p> <p>receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</p> <p>transferring said at least one control signal to said at least one origination transmitter before a specific time; and</p> <p>transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	<p>and processor means controlling the particular ranges and locations wherein said control signals are detected,</p> <p>a buffer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the output functions of said matrix switch means and the transfer functions of said buffer means in response to said control signals.</p>
---	---

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 5,109,414, Claim 13
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u></p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p>transferring said at least one instruct signal to at least one transmitter;</p> <p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a</u></p>	<p>13. In a multichannel television distribution system,</p> <p>a receiver/distribution means for receiving television programming from a multichannel television transmission facility and outputting said programming to a matrix switch means and a control signal detector and processor means,</p> <p>a matrix switch means for receiving said programming from said receiver/distribution means and for outputting selected portions of said received programming to a multichannel television distribution means,</p> <p>a control signal detector and processor means for detecting control signals respecting said programming and transferring said control signals to a buffer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at specified locations within said programming, said control signal detector and processor means controlling the particular ranges and locations wherein said control signals are detected,</p> <p>a buffer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the output functions of said matrix switch means and the transfer functions of said buffer means in response to said</p>

<p>code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and</p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	<p>control signals.</p>
---	-------------------------

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 5,109,414, Claim 13
<p>142. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating only a portion of said video image based on said step of responding to said at least one</u></p>	<p>13. In a multichannel television distribution system, a receiver/distribution means for receiving television programming from a multichannel television transmission facility and outputting said programming to a matrix switch means and a control signal detector and processor means,</p> <p>a matrix switch means for receiving said programming from said receiver/distribution means and for outputting selected portions of said received programming to a multichannel television distribution means,</p> <p>a control signal detector and processor means for detecting control signals respecting said programming and transferring said control signals to a buffer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at specified locations within said programming, said control signal detector and processor means controlling the particular ranges and locations wherein said control signals are detected,</p> <p>a buffer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the output</p>

<u>processor instruction</u> ; and <u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u>	functions of said matrix switch means and the transfer functions of said buffer means in response to said control signals.
---	--

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 5,109,414, Claim 13
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u> receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to <u>processor instructions comprising said organized information,</u> based on said step of organizing; generating a signal based on said processor instructions; and outputting at least a portion of said video presentation based on said generated signal.</p>	<p>13. In a multichannel television distribution system, a receiver/distribution means for receiving television programming from a multichannel television transmission facility and outputting said programming to a matrix switch means and a control signal detector and processor means, a matrix switch means for receiving said programming from said receiver/distribution means and for outputting selected portions of said received programming to a multichannel television distribution means, a control signal detector and processor means for detecting control signals respecting said programming and transferring said control signals to a buffer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at specified locations within said programming, said control signal detector and processor means controlling the particular ranges and locations wherein said control signals are detected, a buffer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the output functions of said matrix switch means and the transfer functions of said buffer means in response to said control signals.</p>

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 5,109,414, Claim 13
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal</u></p>	<p>13. In a multichannel television distribution system, a receiver/distribution means for receiving television programming from a multichannel</p>

<p>detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process <u>downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation</u> and have a target processor to process data, <u>said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station</u>, said method comprising the steps of:</p> <p>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p><u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>television transmission facility and outputting said programming to a matrix switch means and a control signal detector and processor means,</p> <p>a matrix switch means for receiving said programming from said receiver/distribution means and for outputting selected portions of said received programming to a multichannel television distribution means,</p> <p>a control signal detector and processor means for detecting control signals respecting said programming and transferring said control signals to a buffer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at specified locations within said programming, said control signal detector and processor means controlling the particular ranges and locations wherein said control signals are detected,</p> <p>a buffer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the output functions of said matrix switch means and the transfer functions of said buffer means in response to said control signals.</p>
--	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 5,109,414, Claim 13
<p>157. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a video image to be transmitted by a remote</p>	<p>13. In a multichannel television distribution system, a receiver/distribution means for receiving television programming from a multichannel television transmission facility and outputting said programming to a matrix switch means and a control signal detector and processor means,</p> <p>a matrix switch means for receiving said programming from said receiver/distribution means</p>

<p>intermediate transmitter station; <u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u> receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>and for outputting selected portions of said received programming to a multichannel television distribution means, a control signal detector and processor means for detecting control signals respecting said programming and transferring said control signals to a buffer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at specified locations within said programming, said control signal detector and processor means controlling the particular ranges and locations wherein said control signals are detected, a buffer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the output functions of said matrix switch means and the transfer functions of said buffer means in response to said control signals.</p>
---	---

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 5,109,414, Claim 13
<p>162. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of discrete signals, said method comprising the steps of:</u> receiving a video image at a transmitter station; delivering said video image to a transmitter; <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said</u></p>	<p>13. In a multichannel television distribution system, a receiver/distribution means for receiving television programming from a multichannel television transmission facility and outputting said programming to a matrix switch means and a control signal detector and processor means, a matrix switch means for receiving said programming from said receiver/distribution means and for outputting selected portions of said received programming to a multichannel television distribution means, a control signal detector and processor means for detecting control signals respecting said programming and transferring said control signals to a buffer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at specified locations within said programming, said control signal detector and processor means controlling the particular ranges and locations wherein said control signals are detected, a buffer means for receiving and storing said control</p>

<p><u>local image in conjunction with said video image;</u> transferring said at least said first of said plurality of discrete signals to said transmitter; and transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the output functions of said matrix switch means and the transfer functions of said buffer means in response to said control signals.</p>
--	--

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus.

Application Claim 167	U.S. Pat. No. 5,109,414, Claim 13
<p>167. <u>A method of outputting a video graphic presentation</u> at a receiver station including: receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image; passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen; displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen; detecting said at least a first discrete signal of said downloadable code; passing said at least a first discrete signal of said downloadable code to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image;</u> and <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic</u></p>	<p>13. In a multichannel television distribution system, a receiver/distribution means for receiving television programming from a multichannel television transmission facility and outputting said programming to a matrix switch means and a control signal detector and processor means, a matrix switch means for receiving said programming from said receiver/distribution means and for outputting selected portions of said received programming to a multichannel television distribution means, a control signal detector and processor means for detecting control signals respecting said programming and transferring said control signals to a buffer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at specified locations within said programming, said control signal detector and processor means controlling the particular ranges and locations wherein said control signals are detected, a buffer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the output functions of said matrix switch means and the transfer functions of said buffer means in response to said control signals.</p>

<u>image and only a portion of said first completed full-screen video graphic image,</u> wherein said method delivers said video graphic presentation.	
---	--

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 5,109,414, Claim 13
<p>171. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:</u></p> <p style="padding-left: 20px;"><u>receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</u></p> <p style="padding-left: 20px;"><u>transferring said at least one discrete signal to a transmitter;</u></p> <p style="padding-left: 20px;"><u>receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor,</u></p>	<p>13. In a multichannel television distribution system, a receiver/distribution means for receiving television programming from a multichannel television transmission facility and outputting said programming to a matrix switch means and a control signal detector and processor means,</p> <p style="padding-left: 20px;">a matrix switch means for receiving said programming from said receiver/distribution means and for outputting selected portions of said received programming to a multichannel television distribution means,</p> <p style="padding-left: 20px;">a control signal detector and processor means for detecting control signals respecting said programming and transferring said control signals to a buffer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at specified locations within said programming, said control signal detector and processor means controlling the particular ranges and locations wherein said control signals are detected,</p> <p style="padding-left: 20px;">a buffer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p style="padding-left: 20px;">a processor means for controlling the output functions of said matrix switch means and the transfer functions of said buffer means in response to said control signals.</p>

<p><u>said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;</u> transferring said one or more control signals to said transmitter; and transmitting a transmission comprising said at least one discrete signal and said one or more control signals, wherein said method delivers said video graphic presentation.</p>	
---	--

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 5,109,414, Claim 13
<p>175. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of: receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor; <u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said</u></p>	<p>13. In a multichannel television distribution system, a receiver/distribution means for receiving television programming from a multichannel television transmission facility and outputting said programming to a matrix switch means and a control signal detector and processor means, a matrix switch means for receiving said programming from said receiver/distribution means and for outputting selected portions of said received programming to a multichannel television distribution means, a control signal detector and processor means for detecting control signals respecting said programming and transferring said control signals to a buffer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at specified locations within said programming, said control signal detector and processor means controlling the particular ranges and locations wherein said control signals are detected, a buffer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the output functions of said matrix switch means and the transfer functions of said buffer means in response to said control signals.</p>

<p><u>second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</p> <p>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</p> <p>wherein said method delivers said video graphic presentation.</p>	
--	--

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 5,109,414, Claim 13
<p>177. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen</u></p>	<p>13. In a multichannel television distribution system, a receiver/distribution means for receiving television programming from a multichannel television transmission facility and outputting said programming to a matrix switch means and a control signal detector and processor means,</p> <p>a matrix switch means for receiving said programming from said receiver/distribution means and for outputting selected portions of said received programming to a multichannel television distribution means,</p> <p>a control signal detector and processor means for detecting control signals respecting said programming and transferring said control signals to a buffer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at specified locations within said programming, said control signal detector and processor means controlling the particular ranges and locations wherein said control signals are detected,</p> <p>a buffer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the output functions of said matrix switch means and the transfer</p>

<p><u>video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>transferring said one or more instruct signals to said transmitter; and</p> <p>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>functions of said buffer means in response to said control signals.</p>
--	--

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 5,109,414, Claim 13
<p>179. <u>A method of outputting a video graphic presentation</u> at a receiver station including:</p> <p>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</p> <p>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal;</p> <p>passing said at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image;</u> and</p>	<p>13. In a multichannel television distribution system, a receiver/distribution means for receiving television programming from a multichannel television transmission facility and outputting said programming to a matrix switch means and a control signal detector and processor means,</p> <p>a matrix switch means for receiving said programming from said receiver/distribution means and for outputting selected portions of said received programming to a multichannel television distribution means,</p> <p>a control signal detector and processor means for detecting control signals respecting said programming and transferring said control signals to a buffer means, said control signal detector and processor means being configured to detect said control signals in specified frequency ranges or at specified locations within said programming, said control signal detector and processor means controlling the particular ranges and locations wherein said control signals are detected,</p> <p>a buffer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the output functions of said matrix switch means and the transfer functions of said buffer means in response to said control signals.</p>

<p><u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> wherein said method delivers said video graphic presentation.</p>	
--	--

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus.

Application Claim 56	U.S. Pat. No. 5,109,414, Claim 14
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p><u>and</u></p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>14. In a signal processing system,</p> <p>a receiver/distribution means for receiving programming from a program source and for outputting said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distributor means and for directing selected portions of said received programming to a television signal transmission means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a buffer means, said control signal detector means being configured to detect said control signals at a predetermined location within said programming,</p> <p>a buffer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said buffer means based on instructions contained in said control signals.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 5,109,414, Claim 14
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable</u></p>	<p>14. In a signal processing system,</p> <p>a receiver/distribution means for receiving programming from a program source and for outputting said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distributor means and for directing selected portions of said received programming to a television signal transmission means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a buffer means, said control signal detector means being configured to detect said control signals at a predetermined location within said programming,</p> <p>a buffer means for receiving and storing said control signals and for transferring at least a portion of said</p>

<p><u>processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image</u>, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</p> <p>transferring said at least one control signal to said transmitter; and</p> <p>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	<p>control signals to a processor means for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said buffer means based on instructions contained in said control signals.</p>
---	---

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 5,109,414, Claim 14
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</u></p> <p><u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u></p> <p>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</p> <p>transmitting said at least one control signal from</p>	<p>14. In a signal processing system,</p> <p>a receiver/distribution means for receiving programming from a program source and for outputting said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distributor means and for directing selected portions of said received programming to a television signal transmission means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a buffer means, said control signal detector means being configured to detect said control signals at a predetermined location within said programming,</p> <p>a buffer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said buffer means based on instructions contained in said control signals.</p>

said origination transmitter before a specific time.	
--	--

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 5,109,414, Claim 14
<p>84. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, <u>wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals</u> and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <p style="padding-left: 20px;"><u>receiving video at a transmitter station;</u> <u>delivering said video to a transmitter;</u> <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and <u>transmitting said video and said first discrete signal to said at least one receiver station.</u></p>	<p>14. In a signal processing system, a receiver/distribution means for receiving programming from a program source and for outputting said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distributor means and for directing selected portions of said received programming to a television signal transmission means, a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a buffer means, said control signal detector means being configured to detect said control signals at a predetermined location within said programming, a buffer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said buffer means based on instructions contained in said control signals.</p>

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 5,109,414, Claim 14
<p>93. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p>	<p>14. In a signal processing system, a receiver/distribution means for receiving programming from a program source and for outputting said programming to a matrix switch means and a control signal detector means,</p>

<p>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal; detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission; passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor; <u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; <u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>a matrix switch means for receiving said programming from said receiver/distributor means and for directing selected portions of said received programming to a television signal transmission means, a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a buffer means, said control signal detector means being configured to detect said control signals at a predetermined location within said programming, a buffer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said buffer means based on instructions contained in said control signals.</p>
--	--

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 5,109,414, Claim 14
<p>110. A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of: <u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one</u></p>	<p>14. In a signal processing system, a receiver/distribution means for receiving programming from a program source and for outputting said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distributor means and for directing selected portions of said received programming to a television signal transmission means, a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a buffer means, said control signal detector means being configured to detect said</p>

<p><u>processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u> transferring said at least said first discrete signal to at least one transmitter; <u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u> transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>control signals at a predetermined location within said programming, a buffer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said buffer means based on instructions contained in said control signals.</p>
--	---

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 5,109,414, Claim 14
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u> <u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u> receiving at least one control signal which at said remote transmitter station operates to control the</p>	<p>14. In a signal processing system, a receiver/distribution means for receiving programming from a program source and for outputting said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distributor means and for directing selected portions of said received programming to a television signal transmission means, a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a buffer means, said control signal detector means being configured to detect said control signals at a predetermined location within said programming, a buffer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said buffer means based on instructions contained in said control signals.</p>

<p>communication of one of said first discrete signal and said at least one processor instruction; transferring said at least one control signal to said at least one origination transmitter before a specific time; and transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	
---	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 5,109,414, Claim 14
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u> <u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u> transferring said at least one instruct signal to at least one transmitter; <u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an</u></p>	<p>14. In a signal processing system, a receiver/distribution means for receiving programming from a program source and for outputting said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distributor means and for directing selected portions of said received programming to a television signal transmission means, a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a buffer means, said control signal detector means being configured to detect said control signals at a predetermined location within said programming, a buffer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said buffer means based on instructions contained in said control signals.</p>

<p>identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and</p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	
--	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 5,109,414, Claim 14
<p>142. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>14. In a signal processing system,</p> <p>a receiver/distribution means for receiving programming from a program source and for outputting said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distributor means and for directing selected portions of said received programming to a television signal transmission means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a buffer means, said control signal detector means being configured to detect said control signals at a predetermined location within said programming,</p> <p>a buffer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said buffer means based on instructions contained in said control signals.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 5,109,414, Claim 14
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u></p> <ul style="list-style-type: none"> receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to <u>processor instructions comprising said organized information,</u> based on said step of organizing; generating a signal based on said processor instructions; and <u>outputting at least a portion of said video presentation based on said generated signal.</u> 	<p>14. In a signal processing system,</p> <ul style="list-style-type: none"> a receiver/distribution means for receiving programming from a program source and for outputting said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distributor means and for directing selected portions of said received programming to a television signal transmission means, a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a buffer means, said control signal detector means being configured to detect said control signals at a predetermined location within said programming, a buffer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said buffer means based on instructions contained in said control signals.

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 5,109,414, Claim 14
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at</u></p>	<p>14. In a signal processing system,</p> <ul style="list-style-type: none"> a receiver/distribution means for receiving programming from a program source and for outputting said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distributor means and for directing selected portions of said received programming to a television signal transmission means, a control signal detector means for detecting control signals respecting said programming and transferring

<p><u>said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</u></p> <p>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p><u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>said control signals to a buffer means, said control signal detector means being configured to detect said control signals at a predetermined location within said programming,</p> <p>a buffer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said buffer means based on instructions contained in said control signals.</p>
---	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 5,109,414, Claim 14
<p>157. <u>A method of delivering a video presentation at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</u></p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p> <p>receiving, at said origination transmitter station, one</p>	<p>14. In a signal processing system,</p> <p>a receiver/distribution means for receiving programming from a program source and for outputting said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distributor means and for directing selected portions of said received programming to a television signal transmission means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a buffer means, said control signal detector means being configured to detect said control signals at a predetermined location within said programming,</p> <p>a buffer means for receiving and storing said control</p>

<p>or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</p> <p>transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>signals and for transferring at least a portion of said control signals to a processor means for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said buffer means based on instructions contained in said control signals.</p>
---	---

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 5,109,414, Claim 14
<p>162. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals</u>, said method comprising the steps of:</p> <p><u>receiving a video image at a transmitter station;</u></p> <p><u>delivering said video image to a transmitter;</u></p> <p><u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u></p> <p>transferring said at least said first of said plurality of discrete signals to said transmitter; and</p> <p>transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>14. In a signal processing system,</p> <p>a receiver/distribution means for receiving programming from a program source and for outputting said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distributor means and for directing selected portions of said received programming to a television signal transmission means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a buffer means, said control signal detector means being configured to detect said control signals at a predetermined location within said programming,</p> <p>a buffer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said buffer means based on instructions contained in said control signals.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus.

Application Claim 167	U.S. Pat. No. 5,109,414, Claim 14
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</u> <u>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal of said downloadable code;</u> <u>passing said at least a first discrete signal of said downloadable code to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>14. In a signal processing system, a receiver/distribution means for receiving programming from a program source and for outputting said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distributor means and for directing selected portions of said received programming to a television signal transmission means, a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a buffer means, said control signal detector means being configured to detect said control signals at a predetermined location within said programming, a buffer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said buffer means based on instructions contained in said control signals.</p>

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 5,109,414, Claim 14
171. <u>A method of delivering a video graphic</u>	14. In a signal processing system,

presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;

transferring said at least one discrete signal to a transmitter;

receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said at least one discrete signal and said one or more control signals,

wherein said method delivers said video graphic presentation.

a receiver/distribution means for receiving programming from a program source and for outputting said programming to a matrix switch means and a control signal detector means,

a matrix switch means for receiving said programming from said receiver/distributor means and for directing selected portions of said received programming to a television signal transmission means,

a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a buffer means, said control signal detector means being configured to detect said control signals at a predetermined location within said programming,

a buffer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and

a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said buffer means based on instructions contained in said control signals.

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 5,109,414, Claim 14
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</u></p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</u></p> <p><u>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more</u></p>	<p>14. In a signal processing system,</p> <p>a receiver/distribution means for receiving programming from a program source and for outputting said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distributor means and for directing selected portions of said received programming to a television signal transmission means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a buffer means, said control signal detector means being configured to detect said control signals at a predetermined location within said programming,</p> <p>a buffer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said buffer means based on instructions contained in said control signals.</p>

control signals from said origination transmitter before a specific time,
wherein said method delivers said video graphic presentation.

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 5,109,414, Claim 14
<p>177. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p><u>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</u></p> <p><u>delivering said received first completed full-screen video graphic image to a transmitter;</u></p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>transferring said one or more instruct signals to said transmitter; and</u></p> <p><u>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</u></p> <p><u>wherein said method delivers said video graphic</u></p>	<p>14. In a signal processing system,</p> <p>a receiver/distribution means for receiving programming from a program source and for outputting said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distributor means and for directing selected portions of said received programming to a television signal transmission means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a buffer means, said control signal detector means being configured to detect said control signals at a predetermined location within said programming,</p> <p>a buffer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said buffer means based on instructions contained in said control signals.</p>

presentation.

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 5,109,414, Claim 14
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</u> <u>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal;</u> <u>passing said at least a first discrete signal to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>14. In a signal processing system, a receiver/distribution means for receiving programming from a program source and for outputting said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distributor means and for directing selected portions of said received programming to a television signal transmission means, a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a buffer means, said control signal detector means being configured to detect said control signals at a predetermined location within said programming, a buffer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said buffer means based on instructions contained in said control signals.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus.

Application Claim 56	U.S. Pat. No. 5,109,414, Claim 15
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p>and</p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>15. In a signal processing system,</p> <p>a receiver/distribution means for receiving data from a data source and for outputting said data to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said data from said receiver/distributor means and for directing selected portions of said received data to a data transmission means,</p> <p>a control signal detector means for detecting control signals respecting said data and transferring said control signals to a storage/transfer means, said control signal means being configured to detect said control signals at a predetermined location within said data,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means based on instructions contained in said control signals.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 5,109,414, Claim 15
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at</u></p>	<p>15. In a signal processing system,</p> <p>a receiver/distribution means for receiving data from a data source and for outputting said data to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said data from said receiver/distributor means and for directing selected portions of said received data to a data transmission means,</p> <p>a control signal detector means for detecting control signals respecting said data and transferring said control signals to a storage/transfer means, said control signal means being configured to detect said control signals at a predetermined location within said data,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and</p>

<p><u>least one receiver station to generate locally and output said second video image, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</u> transferring said downloadable processor instructions to a transmitter; receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation; transferring said at least one control signal to said transmitter; and transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	<p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means based on instructions contained in said control signals.</p>
---	---

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 5,109,414, Claim 15
<p>80. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of: <u>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>15. In a signal processing system, a receiver/distribution means for receiving data from a data source and for outputting said data to a matrix switch means and a control signal detector means, a matrix switch means for receiving said data from said receiver/distributor means and for directing selected portions of said received data to a data transmission means, a control signal detector means for detecting control signals respecting said data and transferring said control signals to a storage/transfer means, said control signal means being configured to detect said control signals at a predetermined location within said data, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means based on instructions contained in said control signals.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 5,109,414, Claim 15
<p>84. <u>A method of delivering a video presentation at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</u></p> <p style="padding-left: 40px;"><u>receiving video at a transmitter station;</u> <u>delivering said video to a transmitter;</u> <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> <u>transferring said first discrete signal to said transmitter; and</u> <u>transmitting said video and said first discrete signal to said at least one receiver station.</u></p>	<p>15. In a signal processing system,</p> <p style="padding-left: 40px;">a receiver/distribution means for receiving data from a data source and for outputting said data to a matrix switch means and a control signal detector means,</p> <p style="padding-left: 40px;">a matrix switch means for receiving said data from said receiver/distributor means and for directing selected portions of said received data to a data transmission means,</p> <p style="padding-left: 40px;">a control signal detector means for detecting control signals respecting said data and transferring said control signals to a storage/transfer means, said control signal means being configured to detect said control signals at a predetermined location within said data,</p> <p style="padding-left: 40px;">a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and</p> <p style="padding-left: 40px;">a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means based on instructions contained in said control signals.</p>

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 5,109,414, Claim 15
<p>93. <u>A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</u></p> <p style="padding-left: 40px;"><u>receiving at least one information transmission at</u></p>	<p>15. In a signal processing system,</p> <p style="padding-left: 40px;">a receiver/distribution means for receiving data from a data source and for outputting said data to a matrix switch means and a control signal detector means,</p> <p style="padding-left: 40px;">a matrix switch means for receiving said data from</p>

<p>said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal; detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission; passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor; <u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; <u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>said receiver/distributor means and for directing selected portions of said received data to a data transmission means, a control signal detector means for detecting control signals respecting said data and transferring said control signals to a storage/transfer means, said control signal means being configured to detect said control signals at a predetermined location within said data, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means based on instructions contained in said control signals.</p>
---	---

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 5,109,414, Claim 15
<p>110. <u>A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</u> <u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of</u></p>	<p>15. In a signal processing system, a receiver/distribution means for receiving data from a data source and for outputting said data to a matrix switch means and a control signal detector means, a matrix switch means for receiving said data from said receiver/distributor means and for directing selected portions of said received data to a data transmission means, a control signal detector means for detecting control signals respecting said data and transferring said control signals to a storage/transfer means, said control signal means being configured to detect said control signals at a predetermined location within said data,</p>

<p><u>said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u></p> <p>transferring said at least said first discrete signal to at least one transmitter;</p> <p>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</p> <p>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means based on instructions contained in said control signals.</p>
--	---

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 5,109,414, Claim 15
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u></p> <p><u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u></p> <p>receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and</p>	<p>15. In a signal processing system,</p> <p>a receiver/distribution means for receiving data from a data source and for outputting said data to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said data from said receiver/distributor means and for directing selected portions of said received data to a data transmission means,</p> <p>a control signal detector means for detecting control signals respecting said data and transferring said control signals to a storage/transfer means, said control signal means being configured to detect said control signals at a predetermined location within said data,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means based on instructions contained in said control signals.</p>

<p>said at least one processor instruction; transferring said at least one control signal to said at least one origination transmitter before a specific time; and transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	
---	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 5,109,414, Claim 15
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u> <u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u> transferring said at least one instruct signal to at least one transmitter; <u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image</u></p>	<p>15. In a signal processing system, a receiver/distribution means for receiving data from a data source and for outputting said data to a matrix switch means and a control signal detector means, a matrix switch means for receiving said data from said receiver/distributor means and for directing selected portions of said received data to a data transmission means, a control signal detector means for detecting control signals respecting said data and transferring said control signals to a storage/transfer means, said control signal means being configured to detect said control signals at a predetermined location within said data, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means based on instructions contained in said control signals.</p>

<p>and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and</p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	
--	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 5,109,414, Claim 15
<p>142. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>15. In a signal processing system,</p> <p>a receiver/distribution means for receiving data from a data source and for outputting said data to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said data from said receiver/distributor means and for directing selected portions of said received data to a data transmission means,</p> <p>a control signal detector means for detecting control signals respecting said data and transferring said control signals to a storage/transfer means, said control signal means being configured to detect said control signals at a predetermined location within said data,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means based on instructions contained in said control signals.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 5,109,414, Claim 15
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u></p> <ul style="list-style-type: none"> receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to <u>processor instructions comprising said organized information</u>, based on said step of organizing; generating a signal based on said processor instructions; and <u>outputting at least a portion of said video presentation based on said generated signal.</u> 	<p>15. In a signal processing system,</p> <ul style="list-style-type: none"> a receiver/distribution means for receiving data from a data source and for outputting said data to a matrix switch means and a control signal detector means, a matrix switch means for receiving said data from said receiver/distributor means and for directing selected portions of said received data to a data transmission means, a control signal detector means for detecting control signals respecting said data and transferring said control signals to a storage/transfer means, said control signal means being configured to detect said control signals at a predetermined location within said data, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means based on instructions contained in said control signals.

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 5,109,414, Claim 15
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote</u></p>	<p>15. In a signal processing system,</p> <ul style="list-style-type: none"> a receiver/distribution means for receiving data from a data source and for outputting said data to a matrix switch means and a control signal detector means, a matrix switch means for receiving said data from said receiver/distributor means and for directing selected portions of said received data to a data transmission means, a control signal detector means for detecting control signals respecting said data and transferring said control signals to a storage/transfer means, said control signal means being configured to detect said

<p><u>transmitter station</u>, said method comprising the steps of:</p> <p>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p><u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>control signals at a predetermined location within said data,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means based on instructions contained in said control signals.</p>
--	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 5,109,414, Claim 15
<p>157. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p><u>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</u></p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, wherein said one or more</p>	<p>15. In a signal processing system,</p> <p>a receiver/distribution means for receiving data from a data source and for outputting said data to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said data from said receiver/distributor means and for directing selected portions of said received data to a data transmission means,</p> <p>a control signal detector means for detecting control signals respecting said data and transferring said control signals to a storage/transfer means, said control signal means being configured to detect said control signals at a predetermined location within said data,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for</p>

control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and transmitting said one or more control signals from said origination transmitter before a specific time.	further processing, and a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means based on instructions contained in said control signals.
--	---

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 5,109,414, Claim 15
162. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals</u> , said method comprising the steps of: <u>receiving a video image at a transmitter station;</u> <u>delivering said video image to a transmitter;</u> <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> transferring said at least said first of said plurality of discrete signals to said transmitter; and transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.	15. In a signal processing system, a receiver/distribution means for receiving data from a data source and for outputting said data to a matrix switch means and a control signal detector means, a matrix switch means for receiving said data from said receiver/distributor means and for directing selected portions of said received data to a data transmission means, a control signal detector means for detecting control signals respecting said data and transferring said control signals to a storage/transfer means, said control signal means being configured to detect said control signals at a predetermined location within said data, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means based on instructions contained in said control signals.

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus.

Application Claim 167	U.S. Pat. No. 5,109,414, Claim 15
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</u> <u>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal of said downloadable code;</u> <u>passing said at least a first discrete signal of said downloadable code to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>15. In a signal processing system, a receiver/distribution means for receiving data from a data source and for outputting said data to a matrix switch means and a control signal detector means, a matrix switch means for receiving said data from said receiver/distributor means and for directing selected portions of said received data to a data transmission means, a control signal detector means for detecting control signals respecting said data and transferring said control signals to a storage/transfer means, said control signal means being configured to detect said control signals at a predetermined location within said data, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means based on instructions contained in said control signals.</p>

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 5,109,414, Claim 15
171. <u>A method of delivering a video graphic</u>	15. In a signal processing system,

presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;

transferring said at least one discrete signal to a transmitter;

receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said at least one discrete signal and said one or more control signals,

wherein said method delivers said video graphic presentation.

a receiver/distribution means for receiving data from a data source and for outputting said data to a matrix switch means and a control signal detector means,

a matrix switch means for receiving said data from said receiver/distributor means and for directing selected portions of said received data to a data transmission means,

a control signal detector means for detecting control signals respecting said data and transferring said control signals to a storage/transfer means, said control signal means being configured to detect said control signals at a predetermined location within said data,

a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and

a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means based on instructions contained in said control signals.

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 5,109,414, Claim 15
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</u></p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</u></p> <p><u>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more</u></p>	<p>15. In a signal processing system,</p> <p>a receiver/distribution means for receiving data from a data source and for outputting said data to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said data from said receiver/distributor means and for directing selected portions of said received data to a data transmission means,</p> <p>a control signal detector means for detecting control signals respecting said data and transferring said control signals to a storage/transfer means, said control signal means being configured to detect said control signals at a predetermined location within said data,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means based on instructions contained in said control signals.</p>

<u>control signals from said origination transmitter before a specific time,</u> <u>wherein said method delivers said video graphic presentation.</u>	
--	--

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 5,109,414, Claim 15
<p>177. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p><u>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</u></p> <p><u>delivering said received first completed full-screen video graphic image to a transmitter;</u></p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>transferring said one or more instruct signals to said transmitter; and</u></p> <p><u>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</u></p> <p><u>wherein said method delivers said video graphic</u></p>	<p>15. In a signal processing system,</p> <p>a receiver/distribution means for receiving data from a data source and for outputting said data to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said data from said receiver/distributor means and for directing selected portions of said received data to a data transmission means,</p> <p>a control signal detector means for detecting control signals respecting said data and transferring said control signals to a storage/transfer means, said control signal means being configured to detect said control signals at a predetermined location within said data,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and</p> <p>a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means based on instructions contained in said control signals.</p>

presentation.

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 5,109,414, Claim 15
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</u> <u>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal;</u> <u>passing said at least a first discrete signal to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>15. In a signal processing system, a receiver/distribution means for receiving data from a data source and for outputting said data to a matrix switch means and a control signal detector means, a matrix switch means for receiving said data from said receiver/distributor means and for directing selected portions of said received data to a data transmission means, a control signal detector means for detecting control signals respecting said data and transferring said control signals to a storage/transfer means, said control signal means being configured to detect said control signals at a predetermined location within said data, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and a processor means for controlling the directing functions of said matrix switch means and the transfer functions of said storage/transfer means based on instructions contained in said control signals.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus.

Application Claim 56	U.S. Pat. No. 5,109,414, Claim 16
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p>and</p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>16. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a program source and directing said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distribution means and for outputting selected portions of said received programming to a television transmission means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals at predetermined locations within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and</p> <p>a processor means for controlling (1) the output functions of said matrix switch means in response to said control signals, (2) the transfer functions of said storage/transfer means and (3) the predetermined locations within said programming wherein said control signals are detected.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 5,109,414, Claim 16
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable</u></p>	<p>16. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a program source and directing said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distribution means and for outputting selected portions of said received programming to a television transmission means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals at predetermined locations within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a</p>

<p><u>processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</u> transferring said downloadable processor instructions to a transmitter; receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation; transferring said at least one control signal to said transmitter; and transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	<p>portion of said control signals to a processor means for further processing, and a processor means for controlling (1) the output functions of said matrix switch means in response to said control signals, (2) the transfer functions of said storage/transfer means and (3) the predetermined locations within said programming wherein said control signals are detected.</p>
---	---

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 5,109,414, Claim 16
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u> receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station; <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</p>	<p>16. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a program source and directing said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distribution means and for outputting selected portions of said received programming to a television transmission means, a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals at predetermined locations within said programming, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and a processor means for controlling (1) the output functions of said matrix switch means in response to said control signals, (2) the transfer functions of said storage/transfer means and (3) the predetermined</p>

transmitting said at least one control signal from said origination transmitter before a specific time.	locations within said programming wherein said control signals are detected.
---	--

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 5,109,414, Claim 16
<p>84. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <p>receiving video at a transmitter station; delivering said video to a transmitter; <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and transmitting said video and said first discrete signal to said at least one receiver station.</p>	<p>16. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a program source and directing said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distribution means and for outputting selected portions of said received programming to a television transmission means, a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals at predetermined locations within said programming, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and a processor means for controlling (1) the output functions of said matrix switch means in response to said control signals, (2) the transfer functions of said storage/transfer means and (3) the predetermined locations within said programming wherein said control signals are detected.</p>

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 5,109,414, Claim 16
<p>93. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said</p>	<p>16. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a program source and directing said programming to a matrix switch means and a</p>

<p>method comprising the steps of:</p> <p>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal;</p> <p>detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission;</p> <p>passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor;</p> <p><u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/ distribution means and for outputting selected portions of said received programming to a television transmission means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals at predetermined locations within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and</p> <p>a processor means for controlling (1) the output functions of said matrix switch means in response to said control signals, (2) the transfer functions of said storage/transfer means and (3) the predetermined locations within said programming wherein said control signals are detected.</p>
---	---

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 5,109,414, Claim 16
<p>110. A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</p> <p><u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information</u></p>	<p>16. In a multichannel television distribution system,</p> <p>a receiver/distributor means for receiving television programming from a program source and directing said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/ distribution means and for outputting selected portions of said received programming to a television transmission means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to</p>

<p><u>contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u></p> <p>transferring said at least said first discrete signal to at least one transmitter;</p> <p><u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u></p> <p>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>detect said control signals at predetermined locations within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and</p> <p>a processor means for controlling (1) the output functions of said matrix switch means in response to said control signals, (2) the transfer functions of said storage/transfer means and (3) the predetermined locations within said programming wherein said control signals are detected.</p>
---	--

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 5,109,414, Claim 16
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u></p> <p><u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u></p> <p>receiving at least one control signal which at said</p>	<p>16. In a multichannel television distribution system,</p> <p>a receiver/distributor means for receiving television programming from a program source and directing said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distribution means and for outputting selected portions of said received programming to a television transmission means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals at predetermined locations within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and</p> <p>a processor means for controlling (1) the output functions of said matrix switch means in response to said control signals, (2) the transfer functions of said storage/transfer means and (3) the predetermined locations within said programming wherein said</p>

remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction; transferring said at least one control signal to said at least one origination transmitter before a specific time; and transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.	control signals are detected.
--	-------------------------------

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 5,109,414, Claim 16
<p>123. <u>A method of delivering a video presentation</u> at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p>transferring said at least one instruct signal to at least one transmitter;</p> <p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of</u></p>	<p>16. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a program source and directing said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distribution means and for outputting selected portions of said received programming to a television transmission means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals at predetermined locations within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and</p> <p>a processor means for controlling (1) the output functions of said matrix switch means in response to said control signals, (2) the transfer functions of said storage/transfer means and (3) the predetermined locations within said programming wherein said control signals are detected.</p>

<p><u>receiver stations</u>, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and</p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	
--	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 5,109,414, Claim 16
<p>142. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>16. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a program source and directing said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distribution means and for outputting selected portions of said received programming to a television transmission means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals at predetermined locations within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and</p> <p>a processor means for controlling (1) the output functions of said matrix switch means in response to said control signals, (2) the transfer functions of said storage/transfer means and (3) the predetermined locations within said programming wherein said control signals are detected.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 5,109,414, Claim 16
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u></p> <ul style="list-style-type: none"> receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to <u>processor instructions comprising said organized information,</u> based on said step of organizing; generating a signal based on said processor instructions; and outputting at least a portion of said video presentation based on said generated signal. 	<p>16. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a program source and directing said programming to a matrix switch means and a control signal detector means,</p> <ul style="list-style-type: none"> a matrix switch means for receiving said programming from said receiver/distribution means and for outputting selected portions of said received programming to a television transmission means, a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals at predetermined locations within said programming, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and a processor means for controlling (1) the output functions of said matrix switch means in response to said control signals, (2) the transfer functions of said storage/transfer means and (3) the predetermined locations within said programming wherein said control signals are detected.

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 5,109,414, Claim 16
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video</u></p>	<p>16. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a program source and directing said programming to a matrix switch means and a control signal detector means,</p> <ul style="list-style-type: none"> a matrix switch means for receiving said programming from said receiver/distribution means and for outputting selected portions of said received programming to a television transmission means, a control signal detector means for detecting control signals respecting said programming and transferring

<p><u>presentation and a video image which is received at said at least one receiver station from a first remote transmitter station</u>, said method comprising the steps of:</p> <p>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p><u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals at predetermined locations within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and</p> <p>a processor means for controlling (1) the output functions of said matrix switch means in response to said control signals, (2) the transfer functions of said storage/transfer means and (3) the predetermined locations within said programming wherein said control signals are detected.</p>
---	---

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 5,109,414, Claim 16
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p>	<p>16. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a program source and directing said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distribution means and for outputting selected portions of said received programming to a television transmission means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals at predetermined locations within said programming,</p> <p>a storage/transfer means for receiving and storing</p>

<p>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</p> <p>transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and</p> <p>a processor means for controlling (1) the output functions of said matrix switch means in response to said control signals, (2) the transfer functions of said storage/transfer means and (3) the predetermined locations within said programming wherein said control signals are detected.</p>
---	--

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 5,109,414, Claim 16
<p>162. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals</u>, said method comprising the steps of:</u></p> <p>receiving a video image at a transmitter station;</p> <p>delivering said video image to a transmitter;</p> <p><u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u></p> <p>transferring said at least said first of said plurality of discrete signals to said transmitter; and</p> <p>transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>16. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a program source and directing said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distribution means and for outputting selected portions of said received programming to a television transmission means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals at predetermined locations within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and</p> <p>a processor means for controlling (1) the output functions of said matrix switch means in response to said control signals, (2) the transfer functions of said storage/transfer means and (3) the predetermined locations within said programming wherein said control signals are detected.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus.

Application Claim 167	U.S. Pat. No. 5,109,414, Claim 16
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u></p> <p>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</p> <p>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal of said downloadable code;</p> <p>passing said at least a first discrete signal of said downloadable code to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u></p> <p><u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u></p> <p>wherein said method delivers said video graphic presentation.</p>	<p>16. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a program source and directing said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distribution means and for outputting selected portions of said received programming to a television transmission means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals at predetermined locations within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and</p> <p>a processor means for controlling (1) the output functions of said matrix switch means in response to said control signals, (2) the transfer functions of said storage/transfer means and (3) the predetermined locations within said programming wherein said control signals are detected.</p>

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 5,109,414, Claim 16
<p>171. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:</u></p> <p style="padding-left: 2em;"><u>receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</u></p> <p style="padding-left: 2em;"><u>transferring said at least one discrete signal to a transmitter;</u></p> <p style="padding-left: 2em;"><u>receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;</u></p> <p style="padding-left: 2em;"><u>transferring said one or more control signals to said transmitter; and</u></p> <p style="padding-left: 2em;"><u>transmitting a transmission comprising said at least one discrete signal and said one or more control signals,</u></p>	<p>16. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a program source and directing said programming to a matrix switch means and a control signal detector means,</p> <p style="padding-left: 2em;">a matrix switch means for receiving said programming from said receiver/distribution means and for outputting selected portions of said received programming to a television transmission means,</p> <p style="padding-left: 2em;">a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals at predetermined locations within said programming,</p> <p style="padding-left: 2em;">a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and</p> <p style="padding-left: 2em;">a processor means for controlling (1) the output functions of said matrix switch means in response to said control signals, (2) the transfer functions of said storage/transfer means and (3) the predetermined locations within said programming wherein said control signals are detected.</p>

<p>wherein said method delivers said video graphic presentation.</p>	
--	--

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 5,109,414, Claim 16
<p>175. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</p> <p>transmitting a transmission that contains said at</p>	<p>16. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a program source and directing said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distribution means and for outputting selected portions of said received programming to a television transmission means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals at predetermined locations within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and</p> <p>a processor means for controlling (1) the output functions of said matrix switch means in response to said control signals, (2) the transfer functions of said storage/transfer means and (3) the predetermined locations within said programming wherein said control signals are detected.</p>

<p>least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time, wherein said method delivers said video graphic presentation.</p>	
---	--

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 5,109,414, Claim 16
<p>177. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</u> receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor; delivering said received first completed full-screen video graphic image to a transmitter; <u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u> transferring said one or more instruct signals to said transmitter; and transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one</p>	<p>16. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a program source and directing said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distribution means and for outputting selected portions of said received programming to a television transmission means, a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals at predetermined locations within said programming, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and a processor means for controlling (1) the output functions of said matrix switch means in response to said control signals, (2) the transfer functions of said storage/transfer means and (3) the predetermined locations within said programming wherein said control signals are detected.</p>

receiver station, wherein said method delivers said video graphic presentation.	
--	--

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 5,109,414, Claim 16
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u> receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image; passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen; displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen; detecting said at least a first discrete signal; passing said at least a first discrete signal to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> wherein said method delivers said video graphic presentation.</p>	<p>16. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a program source and directing said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distribution means and for outputting selected portions of said received programming to a television transmission means, a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals at predetermined locations within said programming, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and a processor means for controlling (1) the output functions of said matrix switch means in response to said control signals, (2) the transfer functions of said storage/transfer means and (3) the predetermined locations within said programming wherein said control signals are detected.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus.

Application Claim 56	U.S. Pat. No. 5,109,414, Claim 17
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p>and</p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>17. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a program source and directing said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distribution means and for outputting selected portions of said received programming to a recording device operatively connected to a television transmission means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals at predetermined locations within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and</p> <p>a processor means for controlling (1) the output functions of said matrix switch means in response to said control signals, (2) the transfer functions of said storage/transfer means and (3) the predetermined locations within said programming wherein said control signals are detected.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 5,109,414, Claim 17
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a</u></p>	<p>17. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a program source and directing said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distribution means and for outputting selected portions of said received programming to a recording device operatively connected to a television transmission means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals at predetermined locations within said programming,</p>

<p><u>second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image</u>, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</p> <p>transferring said at least one control signal to said transmitter; and</p> <p>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	<p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and</p> <p>a processor means for controlling (1) the output functions of said matrix switch means in response to said control signals, (2) the transfer functions of said storage/transfer means and (3) the predetermined locations within said programming wherein said control signals are detected.</p>
--	---

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 5,109,414, Claim 17
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u></p> <p>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u></p> <p>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said</p>	<p>17. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a program source and directing said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distribution means and for outputting selected portions of said received programming to a recording device operatively connected to a television transmission means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals at predetermined locations within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and</p> <p>a processor means for controlling (1) the output functions of said matrix switch means in response to</p>

instruct signal; and transmitting said at least one control signal from said origination transmitter before a specific time.	said control signals, (2) the transfer functions of said storage/transfer means and (3) the predetermined locations within said programming wherein said control signals are detected.
--	---

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 5,109,414, Claim 17
<p>84. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <p>receiving video at a transmitter station; delivering said video to a transmitter; <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and transmitting said video and said first discrete signal to said at least one receiver station.</p>	<p>17. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a program source and directing said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distribution means and for outputting selected portions of said received programming to a recording device operatively connected to a television transmission means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals at predetermined locations within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and</p> <p>a processor means for controlling (1) the output functions of said matrix switch means in response to said control signals, (2) the transfer functions of said storage/transfer means and (3) the predetermined locations within said programming wherein said control signals are detected.</p>

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 5,109,414, Claim 17
<p>93. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation</p>	<p>17. In a multichannel television distribution system, a receiver/distributor means for receiving television</p>

<p>comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <p>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal;</p> <p>detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission;</p> <p>passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor;</p> <p><u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>programming from a program source and directing said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distribution means and for outputting selected portions of said received programming to a recording device operatively connected to a television transmission means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals at predetermined locations within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and</p> <p>a processor means for controlling (1) the output functions of said matrix switch means in response to said control signals, (2) the transfer functions of said storage/transfer means and (3) the predetermined locations within said programming wherein said control signals are detected.</p>
---	--

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 5,109,414, Claim 17
<p>110. <u>A method of outputting a video presentation</u> at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</p> <p><u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises</u></p>	<p>17. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a program source and directing said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distribution means and for outputting selected portions of said received programming to a recording device operatively connected to a television transmission means,</p> <p>a control signal detector means for detecting control</p>

<p><u>information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u></p> <p>transferring said at least said first discrete signal to at least one transmitter;</p> <p><u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u></p> <p>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals at predetermined locations within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and</p> <p>a processor means for controlling (1) the output functions of said matrix switch means in response to said control signals, (2) the transfer functions of said storage/transfer means and (3) the predetermined locations within said programming wherein said control signals are detected.</p>
---	--

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 5,109,414, Claim 17
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u></p> <p><u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete</u></p>	<p>17. In a multichannel television distribution system,</p> <p>a receiver/distributor means for receiving television programming from a program source and directing said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distribution means and for outputting selected portions of said received programming to a recording device operatively connected to a television transmission means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals at predetermined locations within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and</p> <p>a processor means for controlling (1) the output functions of said matrix switch means in response to</p>

<p><u>signal:</u></p> <p>receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</p> <p>transferring said at least one control signal to said at least one origination transmitter before a specific time; and</p> <p>transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	<p>said control signals, (2) the transfer functions of said storage/transfer means and (3) the predetermined locations within said programming wherein said control signals are detected.</p>
---	---

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 5,109,414, Claim 17
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u></p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p>transferring said at least one instruct signal to at least one transmitter;</p> <p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial</u></p>	<p>17. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a program source and directing said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distribution means and for outputting selected portions of said received programming to a recording device operatively connected to a television transmission means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals at predetermined locations within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and</p> <p>a processor means for controlling (1) the output functions of said matrix switch means in response to said control signals, (2) the transfer functions of said storage/transfer means and (3) the predetermined locations within said programming wherein said control signals are detected.</p>

<p><u>information with information contained in a second discrete signal at said at least one of said plurality of receiver stations</u>, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and</p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	
---	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 5,109,414, Claim 17
<p>142. <u>A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</u></p> <p style="padding-left: 20px;">receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p style="padding-left: 20px;">detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p style="padding-left: 20px;">passing said detected at least a first discrete signal to at least one processor;</p> <p style="padding-left: 20px;"><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p style="padding-left: 20px;">passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p style="padding-left: 20px;">responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p style="padding-left: 20px;"><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u></p> <p style="padding-left: 20px;"><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>17. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a program source and directing said programming to a matrix switch means and a control signal detector means,</p> <p style="padding-left: 20px;">a matrix switch means for receiving said programming from said receiver/distribution means and for outputting selected portions of said received programming to a recording device operatively connected to a television transmission means,</p> <p style="padding-left: 20px;">a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals at predetermined locations within said programming,</p> <p style="padding-left: 20px;">a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and</p> <p style="padding-left: 20px;">a processor means for controlling (1) the output functions of said matrix switch means in response to said control signals, (2) the transfer functions of said storage/transfer means and (3) the predetermined locations within said programming wherein said control signals are detected.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 5,109,414, Claim 17
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u> receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to <u>processor instructions comprising said organized information,</u> based on said step of organizing; generating a signal based on said processor instructions; and outputting at least a portion of said video presentation based on said generated signal.</p>	<p>17. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a program source and directing said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distribution means and for outputting selected portions of said received programming to a recording device operatively connected to a television transmission means, a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals at predetermined locations within said programming, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and a processor means for controlling (1) the output functions of said matrix switch means in response to said control signals, (2) the transfer functions of said storage/transfer means and (3) the predetermined locations within said programming wherein said control signals are detected.</p>

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 5,109,414, Claim 17
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target</u></p>	<p>17. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a program source and directing said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distribution means and for outputting selected portions of said received programming to a recording device operatively</p>

<p>processor to process data, <u>said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station</u>, said method comprising the steps of:</p> <p>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p>receiving <u>said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>connected to a television transmission means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals at predetermined locations within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and</p> <p>a processor means for controlling (1) the output functions of said matrix switch means in response to said control signals, (2) the transfer functions of said storage/transfer means and (3) the predetermined locations within said programming wherein said control signals are detected.</p>
--	---

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 5,109,414, Claim 17
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said</u></p>	<p>17. In a multichannel television distribution system,</p> <p>a receiver/distributor means for receiving television programming from a program source and directing said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distribution means and for outputting selected portions of said received programming to a recording device operatively connected to a television transmission means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to</p>

<p><u>local image is outputted at said at least one receiver station in conjunction with said video image;</u> receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>detect said control signals at predetermined locations within said programming, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and a processor means for controlling (1) the output functions of said matrix switch means in response to said control signals, (2) the transfer functions of said storage/transfer means and (3) the predetermined locations within said programming wherein said control signals are detected.</p>
--	--

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 5,109,414, Claim 17
<p>162. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals; said code comprised of information contained in each of said plurality of discrete signals, said method comprising the steps of:</u> receiving a video image at a transmitter station; delivering said video image to a transmitter; <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> transferring said at least said first of said plurality of discrete signals to said transmitter; and transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>17. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a program source and directing said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distribution means and for outputting selected portions of said received programming to a recording device operatively connected to a television transmission means, a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals at predetermined locations within said programming, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and a processor means for controlling (1) the output functions of said matrix switch means in response to said control signals, (2) the transfer functions of said storage/transfer means and (3) the predetermined locations within said programming wherein said control signals are detected.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus.

Application Claim 167	U.S. Pat. No. 5,109,414, Claim 17
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u></p> <ul style="list-style-type: none"> receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image; passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen; displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen; detecting said at least a first discrete signal of said downloadable code; passing said at least a first discrete signal of said downloadable code to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> wherein said method delivers said video graphic presentation. 	<p>17. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a program source and directing said programming to a matrix switch means and a control signal detector means,</p> <ul style="list-style-type: none"> a matrix switch means for receiving said programming from said receiver/distribution means and for outputting selected portions of said received programming to a recording device operatively connected to a television transmission means, a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals at predetermined locations within said programming, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and a processor means for controlling (1) the output functions of said matrix switch means in response to said control signals, (2) the transfer functions of said storage/transfer means and (3) the predetermined locations within said programming wherein said control signals are detected.

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 5,109,414, Claim 17
<p>171. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:</u></p> <p><u>receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</u></p> <p><u>transferring said at least one discrete signal to a transmitter;</u></p> <p><u>receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first</u></p>	<p>17. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a program source and directing said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distribution means and for outputting selected portions of said received programming to a recording device operatively connected to a television transmission means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals at predetermined locations within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and</p> <p>a processor means for controlling (1) the output functions of said matrix switch means in response to said control signals, (2) the transfer functions of said storage/transfer means and (3) the predetermined locations within said programming wherein said control signals are detected.</p>

<p><u>completed full-screen video graphic image;</u> transferring said one or more control signals to said transmitter; and transmitting a transmission comprising said at least one discrete signal and said one or more control signals, wherein said method delivers said video graphic presentation.</p>	
---	--

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 5,109,414, Claim 17
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u> receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor; <u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u> receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter</p>	<p>17. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a program source and directing said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distribution means and for outputting selected portions of said received programming to a recording device operatively connected to a television transmission means, a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals at predetermined locations within said programming, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and a processor means for controlling (1) the output functions of said matrix switch means in response to said control signals, (2) the transfer functions of said storage/transfer means and (3) the predetermined locations within said programming wherein said control signals are detected.</p>

station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and
transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,
wherein said method delivers said video graphic presentation.

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 5,109,414, Claim 17
<p>177. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic</u></p>	<p>17. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a program source and directing said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distribution means and for outputting selected portions of said received programming to a recording device operatively connected to a television transmission means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals at predetermined locations within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and</p> <p>a processor means for controlling (1) the output functions of said matrix switch means in response to said control signals, (2) the transfer functions of said storage/transfer means and (3) the predetermined locations within said programming wherein said control signals are detected.</p>

<p><u>image;</u> transferring said one or more instruct signals to said transmitter; and transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station, wherein said method delivers said video graphic presentation.</p>	
---	--

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 5,109,414, Claim 17
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u> receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image; passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen; displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen; detecting said at least a first discrete signal; passing said at least a first discrete signal to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said</u></p>	<p>17. In a multichannel television distribution system, a receiver/distributor means for receiving television programming from a program source and directing said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distribution means and for outputting selected portions of said received programming to a recording device operatively connected to a television transmission means, a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals at predetermined locations within said programming, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals to a processor means for further processing, and a processor means for controlling (1) the output functions of said matrix switch means in response to said control signals, (2) the transfer functions of said storage/transfer means and (3) the predetermined locations within said programming wherein said control signals are detected.</p>

<u>second completed full-screen video graphic image</u> <u>and only a portion of said first completed full-screen</u> <u>video graphic image,</u> wherein said method delivers said video graphic presentation.	
---	--

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus.

Application Claim 56	U.S. Pat. No. 5,109,414, Claim 18
<p>56. A method for receiving and processing data for use with an interactive video apparatus, <u>said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source</u>, said method comprising the steps of:</p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p>and</p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>18. A method of communicating data in a system that consists of a plurality of transmission means, a plurality of detectors, a plurality of processors, a switch with means to communicate selected transmissions to selected processors, and a control processor with capacity for controlling the output of said switch, said system being programmed to detect detector identification information and at least some of said detectors being programmed to combine control signal information, consisting of the steps of:</p> <p>transmitting data in a selected transmission,</p> <p>transmitting to said control processor a control signal that causes said processor to control said switch,</p> <p>detecting said control signal at a selected detector, detecting the identification of said selected detector, combining for transmission to said control processor information of said control signal and said detector identification, and</p> <p>causing said control processor to transmit control information to said switch</p> <p>thereby to cause said switch to output at least a portion of said selected transmission to at least one selected processor.</p>

Application Claim 75	U.S. Pat. No. 5,109,414, Claim 18
<p>75. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, <u>said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image</u>, said method comprising the steps of:</p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable</u></p>	<p>18. A method of communicating data in a system that consists of a plurality of transmission means, a plurality of detectors, a plurality of processors, a switch with means to communicate selected transmissions to selected processors, and a control processor with capacity for controlling the output of said switch, said system being programmed to detect detector identification information and at least some of said detectors being programmed to combine control signal information, consisting of the steps of:</p> <p>transmitting data in a selected transmission,</p> <p>transmitting to said control processor a control signal that causes said processor to control said switch,</p> <p>detecting said control signal at a selected detector, detecting the identification of said selected detector, combining for transmission to said control processor information of said control signal and said detector identification, and</p> <p>causing said control processor to transmit control information to said switch</p>

<p>processor instructions having at said at least one receiver station a target processor to process data; transferring said downloadable processor instructions to a transmitter; <u>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</u> transferring said at least one control signal to said transmitter; and transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	<p>thereby to cause said switch to output at least a portion of said selected transmission to at least one selected processor.</p>
--	--

Application Claim 80	U.S. Pat. No. 5,109,414, Claim 18
<p>80. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of: <u>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>18. A method of communicating data in a system that consists of a plurality of transmission means, a plurality of detectors, a plurality of processors, a switch with means to communicate selected transmissions to selected processors, and a control processor with capacity for controlling the output of said switch, said system being programmed to detect detector identification information and at least some of said detectors being programmed to combine control signal information, consisting of the steps of: transmitting data in a selected transmission, transmitting to said control processor a control signal that causes said processor to control said switch, detecting said control signal at a selected detector, detecting the identification of said selected detector, combining for transmission to said control processor information of said control signal and said detector identification, and causing said control processor to transmit control information to said switch thereby to cause said switch to output at least a portion of said selected transmission to at least one selected processor.</p>

Application Claim 84	U.S. Pat. No. 5,109,414, Claim 18
84. A method of delivering a video presentation	18. A method of communicating data in a system

<p>at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <p><u>receiving video at a transmitter station;</u> <u>delivering said video to a transmitter;</u> receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and <u>said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and <u>transmitting said video and said first discrete signal to said at least one receiver station.</u></p>	<p>that consists of a plurality of transmission means, a plurality of detectors, a plurality of processors, a switch with means to communicate selected transmissions to selected processors, and a control processor with capacity for controlling the output of said switch, said system being programmed to detect detector identification information and at least some of said detectors being programmed to combine control signal information, consisting of the steps of:</p> <p>transmitting data in a selected transmission, transmitting to said control processor a control signal that causes said processor to control said switch, detecting said control signal at a selected detector, detecting the identification of said selected detector, combining for transmission to said control processor information of said control signal and said detector identification, and causing said control processor to transmit control information to said switch thereby to cause said switch to output at least a portion of said selected transmission to at least one selected processor.</p>
---	---

Application Claim 93	U.S. Pat. No. 5,109,414, Claim 18
<p>93. A method of outputting a video presentation at a receiver station, <u>said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image,</u> said method comprising the steps of:</p> <p>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal; detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission; passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor; organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal; passing at least one processor instruction from or within said at least one processor, said at least one</p>	<p>18. A method of communicating data in a system that consists of a plurality of transmission means, a plurality of detectors, a plurality of processors, a switch with means to communicate selected transmissions to selected processors, and a control processor with capacity for controlling the output of said switch, said system being programmed to detect detector identification information and at least some of said detectors being programmed to combine control signal information, consisting of the steps of:</p> <p>transmitting data in a selected transmission, transmitting to said control processor a control signal that causes said processor to control said switch, detecting said control signal at a selected detector, detecting the identification of said selected detector, combining for transmission to said control processor information of said control signal and said detector identification, and causing said control processor to transmit control information to said switch</p>

<p>processor instruction comprising said organized information from said step of organizing; responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; <u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>thereby to cause said switch to output at least a portion of said selected transmission to at least one selected processor.</p>
--	--

Application Claim 110	U.S. Pat. No. 5,109,414, Claim 18
<p>110. A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</p> <p>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, <u>said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation</u>, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</p> <p>transferring said at least said first discrete signal to at least one transmitter;</p> <p>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</p> <p>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>18. A method of communicating data in a system that consists of a plurality of transmission means, a plurality of detectors, a plurality of processors, a switch with means to communicate selected transmissions to selected processors, and a control processor with capacity for controlling the output of said switch, said system being programmed to detect detector identification information and at least some of said detectors being programmed to combine control signal information, consisting of the steps of:</p> <p>transmitting data in a selected transmission, transmitting to said control processor a control signal that causes said processor to control said switch,</p> <p>detecting said control signal at a selected detector, detecting the identification of said selected detector, combining for transmission to said control processor information of said control signal and said detector identification, and</p> <p>causing said control processor to transmit control information to said switch</p> <p>thereby to cause said switch to output at least a portion of said selected transmission to at least one selected processor.</p>

Application Claim 116	U.S. Pat. No. 5,109,414, Claim 18
<p>116. A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, <u>wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction</u>, said method comprising the steps of:</p> <p style="padding-left: 2em;"><u>receiving a first discrete signal at an origination transmitter station</u> and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</p> <p style="padding-left: 2em;">receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</p> <p style="padding-left: 2em;"><u>transferring said at least one control signal to said at least one origination transmitter before a specific time;</u></p> <p style="padding-left: 2em;">and</p> <p style="padding-left: 2em;"><u>transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</u></p>	<p>18. A method of communicating data in a system that consists of a plurality of transmission means, a plurality of detectors, a plurality of processors, a switch with means to communicate selected transmissions to selected processors, and a control processor with capacity for controlling the output of said switch, said system being programmed to detect detector identification information and at least some of said detectors being programmed to combine control signal information, consisting of the steps of:</p> <p style="padding-left: 2em;">transmitting data in a selected transmission,</p> <p style="padding-left: 2em;">transmitting to said control processor a control signal that causes said processor to control said switch,</p> <p style="padding-left: 2em;">detecting said control signal at a selected detector,</p> <p style="padding-left: 2em;">detecting the identification of said selected detector,</p> <p style="padding-left: 2em;">combining for transmission to said control processor information of said control signal and said detector identification, and</p> <p style="padding-left: 2em;">causing said control processor to transmit control information to said switch</p> <p style="padding-left: 2em;">thereby to cause said switch to output at least a portion of said selected transmission to at least one selected processor.</p>

Application Claim 123	U.S. Pat. No. 5,109,414, Claim 18
<p>123. A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, <u>wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station</u>, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a</p>	<p>18. A method of communicating data in a system that consists of a plurality of transmission means, a plurality of detectors, a plurality of processors, a switch with means to communicate selected transmissions to selected processors, and a control processor with capacity for controlling the output of said switch, said system being programmed to detect detector identification information and at least some of said detectors being programmed to combine control signal information, consisting of the steps of:</p> <p style="padding-left: 2em;">transmitting data in a selected transmission,</p>

<p>second image and a device, said method comprising the steps of:</p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p>transferring said at least one instruct signal to at least one transmitter;</p> <p>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and</p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	<p>transmitting to said control processor a control signal that causes said processor to control said switch,</p> <p>detecting said control signal at a selected detector, detecting the identification of said selected detector, combining for transmission to said control processor information of said control signal and said detector identification, and</p> <p>causing said control processor to transmit control information to said switch</p> <p>thereby to cause said switch to output at least a portion of said selected transmission to at least one selected processor.</p>
--	--

Application Claim 142	U.S. Pat. No. 5,109,414, Claim 18
<p>142. A method of outputting a video presentation at a receiver station, <u>said video presentation including a video image</u>, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p>organizing information contained in said at least a</p>	<p>18. A method of communicating data in a system that consists of a plurality of transmission means, a plurality of detectors, a plurality of processors, a switch with means to communicate selected transmissions to selected processors, and a control processor with capacity for controlling the output of said switch, said system being programmed to detect detector identification information and at least some of said detectors being programmed to combine control signal information, consisting of the steps of:</p> <p>transmitting data in a selected transmission,</p> <p>transmitting to said control processor a control signal that causes said processor to control said</p>

<p>first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</p> <p>passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;</p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>switch,</p> <p>detecting said control signal at a selected detector, detecting the identification of said selected detector, combining for transmission to said control processor information of said control signal and said detector identification, and</p> <p>causing said control processor to transmit control information to said switch</p> <p>thereby to cause said switch to output at least a portion of said selected transmission to at least one selected processor.</p>
--	---

Application Claim 143	U.S. Pat. No. 5,109,414, Claim 18
<p>143. A method of outputting a video presentation at a receiver station including:</p> <p><u>receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal;</u></p> <p><u>passing said received video image to an output device for delivery to a user;</u></p> <p>detecting said at least one first discrete signal;</p> <p>passing information contained in said at least one first discrete signal to a processor in response to said step of detecting;</p> <p>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</p> <p>responding, at said processor, to processor instructions comprising said organized information, based on said step of organizing;</p> <p>generating a signal based on said processor instructions; and</p> <p><u>outputting at least a portion of said video presentation based on said generated signal.</u></p>	<p>18. A method of communicating data in a system that consists of a plurality of transmission means, a plurality of detectors, a plurality of processors, a switch with means to communicate selected transmissions to selected processors, and a control processor with capacity for controlling the output of said switch, said system being programmed to detect detector identification information and at least some of said detectors being programmed to combine control signal information, consisting of the steps of:</p> <p>transmitting data in a selected transmission,</p> <p>transmitting to said control processor a control signal that causes said processor to control said switch,</p> <p>detecting said control signal at a selected detector, detecting the identification of said selected detector, combining for transmission to said control processor information of said control signal and said detector identification, and</p> <p>causing said control processor to transmit control information to said switch</p> <p>thereby to cause said switch to output at least a portion of said selected transmission to at least one selected processor.</p>

Application Claim 152	U.S. Pat. No. 5,109,414, Claim 18
<p>152. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is</p>	<p>18. A method of communicating data in a system that consists of a plurality of transmission means, a plurality of detectors, a plurality of processors, a switch with means to communicate selected</p>

<p>adapted to detect the presence of one or more control signals and programmed to process <u>downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</u></p> <p>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p><u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>transmissions to selected processors, and a control processor with capacity for controlling the output of said switch, said system being programmed to detect detector identification information and at least some of said detectors being programmed to combine control signal information, consisting of the steps of:</p> <p>transmitting data in a selected transmission,</p> <p>transmitting to said control processor a control signal that causes said processor to control said switch,</p> <p>detecting said control signal at a selected detector, detecting the identification of said selected detector, combining for transmission to said control processor information of said control signal and said detector identification, and</p> <p>causing said control processor to transmit control information to said switch</p> <p>thereby to cause said switch to output at least a portion of said selected transmission to at least one selected processor.</p>
---	--

Application Claim 157	U.S. Pat. No. 5,109,414, Claim 18
<p>157. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p><u>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</u></p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a</u></p>	<p>18. A method of communicating data in a system that consists of a plurality of transmission means, a plurality of detectors, a plurality of processors, a switch with means to communicate selected transmissions to selected processors, and a control processor with capacity for controlling the output of said switch, said system being programmed to detect detector identification information and at least some of said detectors being programmed to combine control signal information, consisting of the steps of:</p> <p>transmitting data in a selected transmission,</p> <p>transmitting to said control processor a control signal that causes said processor to control said</p>

<p><u>local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image:</u></p> <p>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</p> <p>transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>switch,</p> <p>detecting said control signal at a selected detector, detecting the identification of said selected detector, combining for transmission to said control processor information of said control signal and said detector identification, and</p> <p>causing said control processor to transmit control information to said switch</p> <p>thereby to cause said switch to output at least a portion of said selected transmission to at least one selected processor.</p>
---	---

Application Claim 162	U.S. Pat. No. 5,109,414, Claim 18
<p>162. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of discrete signals, said method comprising the steps of:</p> <p><u>receiving a video image at a transmitter station;</u></p> <p><u>delivering said video image to a transmitter;</u></p> <p>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and <u>wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u></p> <p>transferring said at least said first of said plurality of discrete signals to said transmitter; and</p> <p><u>transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</u></p>	<p>18. A method of communicating data in a system that consists of a plurality of transmission means, a plurality of detectors, a plurality of processors, a switch with means to communicate selected transmissions to selected processors, and a control processor with capacity for controlling the output of said switch, said system being programmed to detect detector identification information and at least some of said detectors being programmed to combine control signal information, consisting of the steps of:</p> <p>transmitting data in a selected transmission,</p> <p>transmitting to said control processor a control signal that causes said processor to control said switch,</p> <p>detecting said control signal at a selected detector, detecting the identification of said selected detector, combining for transmission to said control processor information of said control signal and said detector identification, and</p> <p>causing said control processor to transmit control information to said switch</p> <p>thereby to cause said switch to output at least a portion of said selected transmission to at least one selected processor.</p>

Application Claim 167	U.S. Pat. No. 5,109,414, Claim 18
<p>167. A method of outputting a video graphic presentation at a receiver station including:</p> <p><u>receiving, from a remote transmitter station, a</u></p>	<p>18. A method of communicating data in a system that consists of a plurality of transmission means, a plurality of detectors, a plurality of processors, a</p>

transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;

passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;

displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;

detecting said at least a first discrete signal of said downloadable code;

passing said at least a first discrete signal of said downloadable code to at least one processor;

organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;

responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;

passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and

displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,

wherein said method delivers said video graphic presentation.

switch with means to communicate selected transmissions to selected processors, and a control processor with capacity for controlling the output of said switch, said system being programmed to detect detector identification information and at least some of said detectors being programmed to combine control signal information, consisting of the steps of:

- transmitting data in a selected transmission,
- transmitting to said control processor a control signal that causes said processor to control said switch,

- detecting said control signal at a selected detector, detecting the identification of said selected detector, combining for transmission to said control processor information of said control signal and said detector identification, and

- causing said control processor to transmit control information to said switch

thereby to cause said switch to output at least a portion of said selected transmission to at least one selected processor.

Application Claim 171	U.S. Pat. No. 5,109,414, Claim 18
<p>171. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, <u>wherein said at least one processor instruction instructs said at least one receiver station to</u></p>	<p>18. A method of communicating data in a system that consists of a plurality of transmission means, a plurality of detectors, a plurality of processors, a switch with means to communicate selected transmissions to selected processors, and a control processor with capacity for controlling the output of said switch, said system being programmed to detect detector identification information and at least some of said detectors being programmed to combine control signal information, consisting of the steps of:</p>

<p><u>pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:</u></p> <p>receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</p> <p>transferring said at least one discrete signal to a transmitter;</p> <p>receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, <u>said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said at least one discrete signal and said one or more control signals,</p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>transmitting data in a selected transmission, transmitting to said control processor a control signal that causes said processor to control said switch,</p> <p>detecting said control signal at a selected detector, detecting the identification of said selected detector, combining for transmission to said control processor information of said control signal and said detector identification, and</p> <p>causing said control processor to transmit control information to said switch</p> <p>thereby to cause said switch to output at least a portion of said selected transmission to at least one selected processor.</p>
---	--

Application Claim 175	U.S. Pat. No. 5,109,414, Claim 18
<p>175. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver,</p>	<p>18. A method of communicating data in a system that consists of a plurality of transmission means, a plurality of detectors, a plurality of processors, a switch with means to communicate selected transmissions to selected processors, and a control</p>

<p>a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</p> <p><u>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</u></p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</p> <p><u>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>processor with capacity for controlling the output of said switch, said system being programmed to detect detector identification information and at least some of said detectors being programmed to combine control signal information, consisting of the steps of:</p> <p>transmitting data in a selected transmission,</p> <p>transmitting to said control processor a control signal that causes said processor to control said switch,</p> <p>detecting said control signal at a selected detector, detecting the identification of said selected detector, combining for transmission to said control processor information of said control signal and said detector identification, and</p> <p>causing said control processor to transmit control information to said switch</p> <p>thereby to cause said switch to output at least a portion of said selected transmission to at least one selected processor.</p>
--	--

Application Claim 177	U.S. Pat. No. 5,109,414, Claim 18
<p>177. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the</p>	<p>18. A method of communicating data in a system that consists of a plurality of transmission means, a plurality of detectors, a plurality of processors, a switch with means to communicate selected transmissions to selected processors, and a control processor with capacity for controlling the output of</p>

<p>presence of signals, said method comprising the steps of:</p> <p><u>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</u></p> <p><u>delivering said received first completed full-screen video graphic image to a transmitter;</u></p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>transferring said one or more instruct signals to said transmitter; and</u></p> <p><u>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>said switch, said system being programmed to detect detector identification information and at least some of said detectors being programmed to combine control signal information, consisting of the steps of:</p> <p style="padding-left: 20px;">transmitting data in a selected transmission,</p> <p style="padding-left: 20px;">transmitting to said control processor a control signal that causes said processor to control said switch,</p> <p style="padding-left: 20px;">detecting said control signal at a selected detector, detecting the identification of said selected detector, combining for transmission to said control processor information of said control signal and said detector identification, and</p> <p style="padding-left: 20px;">causing said control processor to transmit control information to said switch</p> <p style="padding-left: 20px;">thereby to cause said switch to output at least a portion of said selected transmission to at least one selected processor.</p>
--	--

Application Claim 179	U.S. Pat. No. 5,109,414, Claim 18
<p>179. A method of outputting a video graphic presentation at a receiver station including:</p> <p><u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</u></p> <p><u>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</u></p> <p><u>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface</u></p>	<p>18. A method of communicating data in a system that consists of a plurality of transmission means, a plurality of detectors, a plurality of processors, a switch with means to communicate selected transmissions to selected processors, and a control processor with capacity for controlling the output of said switch, said system being programmed to detect detector identification information and at least some of said detectors being programmed to combine control signal information, consisting of the steps of:</p> <p style="padding-left: 20px;">transmitting data in a selected transmission,</p> <p style="padding-left: 20px;">transmitting to said control processor a control signal that causes said processor to control said</p>

<p><u>area of said viewing screen;</u> detecting said at least a first discrete signal; passing said at least a first discrete signal to at least one processor; organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal; responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing; <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>switch, detecting said control signal at a selected detector, detecting the identification of said selected detector, combining for transmission to said control processor information of said control signal and said detector identification, and causing said control processor to transmit control information to said switch thereby to cause said switch to output at least a portion of said selected transmission to at least one selected processor.</p>
--	--

Application Claim 56	U.S. Pat. No. 5,109,414, Claim 19
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p>and</p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>19. In a method of communicating data in a system that consists of a plurality of transmission means, a plurality of detectors, a plurality of processors, a switch with means to communicate selected transmissions to selected processors, and a control processor with capacity for controlling the output of said switch, wherein at least some of said detectors are programmed to combine control signal information for transmission to said control processor and to transmit detector identification information, consisting of the steps of:</p> <p>transmitting data in a selected transmission,</p> <p>transmitting to said control processor a control signal that causes said control processor to control said switch, and</p> <p>thereby causing a selected detector to combine for transmission to said control processor information of said control signal and detector identification information, said control processor to transmit control information to said switch, and said switch to input data of said selected transmission to at least one selected processor.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations in an operating environment of a transmitter station.

Application Claim 75	U.S. Pat. No. 5,109,414, Claim 19
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at</u></p>	<p>19. In a method of communicating data in a system that consists of a plurality of transmission means, a plurality of detectors, a plurality of processors, a switch with means to communicate selected transmissions to selected processors, and a control processor with capacity for controlling the output of said switch, wherein at least some of said detectors are programmed to combine control signal information for transmission to said control processor and to transmit detector identification information, consisting of the steps of:</p> <p>transmitting data in a selected transmission,</p> <p>transmitting to said control processor a control signal that causes said control processor to control said switch, and</p> <p>thereby causing a selected detector to combine for transmission to said control processor information of said control signal and detector identification information, said control processor to transmit control</p>

<p>least one receiver station to generate locally and output said second video image, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</p> <p>transferring said at least one control signal to said transmitter; and</p> <p>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	<p>information to said switch, and said switch to input data of said selected transmission to at least one selected processor.</p>
--	--

Application Claim 80	U.S. Pat. No. 5,109,414, Claim 19
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</u></p> <p><u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u></p> <p>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</p> <p>transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>19. In a method of communicating data in a system that consists of a plurality of transmission means, a plurality of detectors, a plurality of processors, a switch with means to communicate selected transmissions to selected processors, and a control processor with capacity for controlling the output of said switch, wherein at least some of said detectors are programmed to combine control signal information for transmission to said control processor and to transmit detector identification information, consisting of the steps of:</p> <p>transmitting data in a selected transmission,</p> <p>transmitting to said control processor a control signal that causes said control processor to control said switch, and</p> <p>thereby causing a selected detector to combine for transmission to said control processor information of said control signal and detector identification information, said control processor to transmit control information to said switch, and said switch to input data of said selected transmission to at least one selected processor.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter

station and a receiver station. This differentiates claim 80 over the patented claim's recitations in an operating environment of a transmitter station.

Application Claim 84	U.S. Pat. No. 5,109,414, Claim 19
<p>84. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <p><u>receiving video at a transmitter station;</u> <u>delivering said video to a transmitter;</u> receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and <u>said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and <u>transmitting said video and said first discrete signal to said at least one receiver station.</u></p>	<p>19. In a method of communicating data in a system that consists of a plurality of transmission means, a plurality of detectors, a plurality of processors, a switch with means to communicate selected transmissions to selected processors, and a control processor with capacity for controlling the output of said switch, wherein at least some of said detectors are programmed to combine control signal information for transmission to said control processor and to transmit detector identification information, consisting of the steps of:</p> <p>transmitting data in a selected transmission, transmitting to said control processor a control signal that causes said control processor to control said switch, and thereby causing a selected detector to combine for transmission to said control processor information of said control signal and detector identification information, said control processor to transmit control information to said switch, and said switch to input data of said selected transmission to at least one selected processor.</p>

Application Claim 93	U.S. Pat. No. 5,109,414, Claim 19
<p>93. A method of outputting a video presentation at a receiver station, <u>said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image,</u> said method comprising the steps of:</p> <p>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal; detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission; passing said detected at least one first discrete signal and said detected at least one control signal to at least</p>	<p>19. In a method of communicating data in a system that consists of a plurality of transmission means, a plurality of detectors, a plurality of processors, a switch with means to communicate selected transmissions to selected processors, and a control processor with capacity for controlling the output of said switch, wherein at least some of said detectors are programmed to combine control signal information for transmission to said control processor and to transmit detector identification information, consisting of the steps of:</p> <p>transmitting data in a selected transmission, transmitting to said control processor a control signal that causes said control processor to control said</p>

<p>one processor;</p> <p>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</p> <p>passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;</p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>switch, and</p> <p>thereby causing a selected detector to combine for transmission to said control processor information of said control signal and detector identification information, said control processor to transmit control information to said switch, and said switch to input data of said selected transmission to at least one selected processor.</p>
---	--

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations in an operating environment of a transmitter station.

Application Claim 110	U.S. Pat. No. 5,109,414, Claim 19
<p>110. A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</p> <p>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, <u>said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation</u>, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</p> <p>transferring said at least said first discrete signal to at least one transmitter;</p> <p>receiving said at least one control signal at said at least one transmitter station, wherein said at least one</p>	<p>19. In a method of communicating data in a system that consists of a plurality of transmission means, a plurality of detectors, a plurality of processors, a switch with means to communicate selected transmissions to selected processors, and a control processor with capacity for controlling the output of said switch, wherein at least some of said detectors are programmed to combine control signal information for transmission to said control processor and to transmit detector identification information, consisting of the steps of:</p> <p>transmitting data in a selected transmission,</p> <p>transmitting to said control processor a control signal that causes said control processor to control said switch, and</p> <p>thereby causing a selected detector to combine for transmission to said control processor information of said control signal and detector identification information, said control processor to transmit control information to said switch, and said switch to input data of said selected transmission to at least one selected processor.</p>

control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.	
--	--

Application Claim 116	U.S. Pat. No. 5,109,414, Claim 19
<p>116. <u>A method of delivering a video presentation</u> at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, <u>wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction</u>, said method comprising the steps of:</p> <p>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</p> <p>receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</p> <p><u>transferring said at least one control signal to said at least one origination transmitter before a specific time;</u> and</p> <p><u>transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</u></p>	<p>19. In a method of communicating data in a system that consists of a plurality of transmission means, a plurality of detectors, a plurality of processors, a switch with means to communicate selected transmissions to selected processors, and a control processor with capacity for controlling the output of said switch, wherein at least some of said detectors are programmed to combine control signal information for transmission to said control processor and to transmit detector identification information, consisting of the steps of:</p> <p>transmitting data in a selected transmission,</p> <p>transmitting to said control processor a control signal that causes said control processor to control said switch, and</p> <p>thereby causing a selected detector to combine for transmission to said control processor information of said control signal and detector identification information, said control processor to transmit control information to said switch, and said switch to input data of said selected transmission to at least one selected processor.</p>

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations in an operating environment of a transmitter station.

Application Claim 123	U.S. Pat. No. 5,109,414, Claim 19
<p>123. A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, <u>wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station</u>, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</p> <p style="padding-left: 2em;">receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</p> <p style="padding-left: 2em;">transferring said at least one instruct signal to at least one transmitter;</p> <p style="padding-left: 2em;">receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and</p> <p style="padding-left: 2em;">transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	<p>19. In a method of communicating data in a system that consists of a plurality of transmission means, a plurality of detectors, a plurality of processors, a switch with means to communicate selected transmissions to selected processors, and a control processor with capacity for controlling the output of said switch, wherein at least some of said detectors are programmed to combine control signal information for transmission to said control processor and to transmit detector identification information, consisting of the steps of:</p> <p style="padding-left: 2em;">transmitting data in a selected transmission, transmitting to said control processor a control signal that causes said control processor to control said switch, and</p> <p style="padding-left: 2em;">thereby causing a selected detector to combine for transmission to said control processor information of said control signal and detector identification information, said control processor to transmit control information to said switch, and said switch to input data of said selected transmission to at least one selected processor.</p>

Application Claim 142	U.S. Pat. No. 5,109,414, Claim 19
<p>142. <u>A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</u></p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</p> <p>passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;</p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>19. In a method of communicating data in a system that consists of a plurality of transmission means, a plurality of detectors, a plurality of processors, a switch with means to communicate selected transmissions to selected processors, and a control processor with capacity for controlling the output of said switch, wherein at least some of said detectors are programmed to combine control signal information for transmission to said control processor and to transmit detector identification information, consisting of the steps of:</p> <p>transmitting data in a selected transmission,</p> <p>transmitting to said control processor a control signal that causes said control processor to control said switch, and</p> <p>thereby causing a selected detector to combine for transmission to said control processor information of said control signal and detector identification information, said control processor to transmit control information to said switch, and said switch to input data of said selected transmission to at least one selected processor.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations in an operating environment of a transmitter station.

Application Claim 143	U.S. Pat. No. 5,109,414, Claim 19
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u></p> <p><u>receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal;</u></p> <p><u>passing said received video image to an output device for delivery to a user;</u></p> <p>detecting said at least one first discrete signal;</p> <p>passing information contained in said at least one first discrete signal to a processor in response to said step of detecting;</p> <p>organizing said information contained in said at least one first discrete signal at said receiver station</p>	<p>19. In a method of communicating data in a system that consists of a plurality of transmission means, a plurality of detectors, a plurality of processors, a switch with means to communicate selected transmissions to selected processors, and a control processor with capacity for controlling the output of said switch, wherein at least some of said detectors are programmed to combine control signal information for transmission to said control processor and to transmit detector identification information, consisting of the steps of:</p> <p>transmitting data in a selected transmission,</p> <p>transmitting to said control processor a control</p>

<p>with information contained in at least one second discrete signal; responding, at said processor, to processor instructions comprising said organized information, based on said step of organizing; generating a signal based on said processor instructions; and <u>outputting at least a portion of said video presentation based on said generated signal.</u></p>	<p>signal that causes said control processor to control said switch, and thereby causing a selected detector to combine for transmission to said control processor information of said control signal and detector identification information, said control processor to transmit control information to said switch, and said switch to input data of said selected transmission to at least one selected processor.</p>
--	--

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations in an operating environment of a transmitter station.

Application Claim 152	U.S. Pat. No. 5,109,414, Claim 19
<p>152. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process <u>downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation</u> and have a target processor to process data, <u>said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station</u>, said method comprising the steps of:</p> <p>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions; transferring said downloadable processor instructions to a transmitter; receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and <u>wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u> transferring said one or more control signals to said transmitter; and</p>	<p>19. In a method of communicating data in a system that consists of a plurality of transmission means, a plurality of detectors, a plurality of processors, a switch with means to communicate selected transmissions to selected processors, and a control processor with capacity for controlling the output of said switch, wherein at least some of said detectors are programmed to combine control signal information for transmission to said control processor and to transmit detector identification information, consisting of the steps of:</p> <p>transmitting data in a selected transmission, transmitting to said control processor a control signal that causes said control processor to control said switch, and thereby causing a selected detector to combine for transmission to said control processor information of said control signal and detector identification information, said control processor to transmit control information to said switch, and said switch to input data of said selected transmission to at least one selected processor.</p>

transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.	
---	--

Application Claim 157	U.S. Pat. No. 5,109,414, Claim 19
<p>157. <u>A method of delivering a video presentation at at least one receiver station</u> of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p><u>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</u></p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</p> <p>transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>19. In a method of communicating data in a system that consists of a plurality of transmission means, a plurality of detectors, a plurality of processors, a switch with means to communicate selected transmissions to selected processors, and a control processor with capacity for controlling the output of said switch, wherein at least some of said detectors are programmed to combine control signal information for transmission to said control processor and to transmit detector identification information, consisting of the steps of:</p> <p>transmitting data in a selected transmission,</p> <p>transmitting to said control processor a control signal that causes said control processor to control said switch, and</p> <p>thereby causing a selected detector to combine for transmission to said control processor information of said control signal and detector identification information, said control processor to transmit control information to said switch, and said switch to input data of said selected transmission to at least one selected processor.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations in an operating environment of a transmitter station.

Application Claim 162	U.S. Pat. No. 5,109,414, Claim 19
<p>162. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of discrete signals, said method comprising the steps of:</p> <p><u>receiving a video image at a transmitter station;</u></p>	<p>19. In a method of communicating data in a system that consists of a plurality of transmission means, a plurality of detectors, a plurality of processors, a switch with means to communicate selected transmissions to selected processors, and a control processor with capacity for controlling the output of said switch, wherein at least some of said detectors are programmed to combine control signal information for transmission to said control processor and to transmit detector identification information, consisting</p>

<p><u>delivering said video image to a transmitter;</u> receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and <u>wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> transferring said at least said first of said plurality of discrete signals to said transmitter; and transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>of the steps of: transmitting data in a selected transmission, transmitting to said control processor a control signal that causes said control processor to control said switch, and thereby causing a selected detector to combine for transmission to said control processor information of said control signal and detector identification information, said control processor to transmit control information to said switch, and said switch to input data of said selected transmission to at least one selected processor.</p>
--	--

Application Claim 167	U.S. Pat. No. 5,109,414, Claim 19
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</u> <u>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> detecting said at least a first discrete signal of said downloadable code; passing said at least a first discrete signal of said downloadable code to at least one processor; organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal; responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing; <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a</u></p>	<p>19. In a method of communicating data in a system that consists of a plurality of transmission means, a plurality of detectors, a plurality of processors, a switch with means to communicate selected transmissions to selected processors, and a control processor with capacity for controlling the output of said switch, wherein at least some of said detectors are programmed to combine control signal information for transmission to said control processor and to transmit detector identification information, consisting of the steps of: transmitting data in a selected transmission, transmitting to said control processor a control signal that causes said control processor to control said switch, and thereby causing a selected detector to combine for transmission to said control processor information of said control signal and detector identification information, said control processor to transmit control information to said switch, and said switch to input data of said selected transmission to at least one selected processor.</p>

<p><u>portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	
--	--

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations in an operating environment of a transmitter station.

Application Claim 171	U.S. Pat. No. 5,109,414, Claim 19
<p>171. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, <u>wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image,</u> said method comprising the steps of:</p> <p>receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</p> <p>transferring said at least one discrete signal to a transmitter;</p> <p>receiving said one or more control signals at said</p>	<p>19. In a method of communicating data in a system that consists of a plurality of transmission means, a plurality of detectors, a plurality of processors, a switch with means to communicate selected transmissions to selected processors, and a control processor with capacity for controlling the output of said switch, wherein at least some of said detectors are programmed to combine control signal information for transmission to said control processor and to transmit detector identification information, consisting of the steps of:</p> <p>transmitting data in a selected transmission,</p> <p>transmitting to said control processor a control signal that causes said control processor to control said switch, and</p> <p>thereby causing a selected detector to combine for transmission to said control processor information of said control signal and detector identification information, said control processor to transmit control information to said switch, and said switch to input data of said selected transmission to at least one selected processor.</p>

<p>transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, <u>said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;</u> transferring said one or more control signals to said transmitter; and transmitting a transmission comprising said at least one discrete signal and said one or more control signals, <u>wherein said method delivers said video graphic presentation.</u></p>	
--	--

Application Claim 175	U.S. Pat. No. 5,109,414, Claim 19
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</u> <u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with</u></p>	<p>19. In a method of communicating data in a system that consists of a plurality of transmission means, a plurality of detectors, a plurality of processors, a switch with means to communicate selected transmissions to selected processors, and a control processor with capacity for controlling the output of said switch, wherein at least some of said detectors are programmed to combine control signal information for transmission to said control processor and to transmit detector identification information, consisting of the steps of: transmitting data in a selected transmission, transmitting to said control processor a control signal that causes said control processor to control said switch, and thereby causing a selected detector to combine for transmission to said control processor information of said control signal and detector identification information, said control processor to transmit control information to said switch, and said switch to input data of said selected transmission to at least one selected processor.</p>

<p><u>only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</p> <p><u>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	
--	--

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations in an operating environment of a transmitter station.

Application Claim 177	U.S. Pat. No. 5,109,414, Claim 19
<p>177. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p><u>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</u></p> <p><u>delivering said received first completed full-screen video graphic image to a transmitter;</u></p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen</u></p>	<p>19. In a method of communicating data in a system that consists of a plurality of transmission means, a plurality of detectors, a plurality of processors, a switch with means to communicate selected transmissions to selected processors, and a control processor with capacity for controlling the output of said switch, wherein at least some of said detectors are programmed to combine control signal information for transmission to said control processor and to transmit detector identification information, consisting of the steps of:</p> <p>transmitting data in a selected transmission,</p> <p>transmitting to said control processor a control signal that causes said control processor to control said switch, and</p> <p>thereby causing a selected detector to combine for transmission to said control processor information of said control signal and detector identification information, said control processor to transmit control information to said switch, and said switch to input data of said selected transmission to at least one selected processor.</p>

<p><u>when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>transferring said one or more instruct signals to said transmitter; and</p> <p><u>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	
--	--

Application Claim 179	U.S. Pat. No. 5,109,414, Claim 19
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u></p> <p><u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</u></p> <p><u>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</u></p> <p><u>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u></p> <p>detecting said at least a first discrete signal;</p> <p>passing said at least a first discrete signal to at least one processor;</p> <p>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</p> <p>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u></p> <p><u>displaying said second completed full-screen video graphic image at said video monitor, said displayed</u></p>	<p>19. In a method of communicating data in a system that consists of a plurality of transmission means, a plurality of detectors, a plurality of processors, a switch with means to communicate selected transmissions to selected processors, and a control processor with capacity for controlling the output of said switch, wherein at least some of said detectors are programmed to combine control signal information for transmission to said control processor and to transmit detector identification information, consisting of the steps of:</p> <p>transmitting data in a selected transmission,</p> <p>transmitting to said control processor a control signal that causes said control processor to control said switch, and</p> <p>thereby causing a selected detector to combine for transmission to said control processor information of said control signal and detector identification information, said control processor to transmit control information to said switch, and said switch to input data of said selected transmission to at least one selected processor.</p>

<u>second completed full-screen video graphic image</u> <u>filling the entire surface area of said viewing screen</u> <u>and containing said passed only said portion of said</u> <u>second completed full-screen video graphic image and</u> <u>only a portion of said first completed full-screen video</u> <u>graphic image,</u> <u>wherein said method delivers said video graphic</u> <u>presentation.</u>	
--	--

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations in an operating environment of a transmitter station.

Application Claim 56	U.S. Pat. No. 5,109,414, Claim 21
<p>56. A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying <u>a video presentation comprising a locally generated image and an image received from a remote video source</u>, said method comprising the steps of:</p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p>and</p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>21. A method of communicating television programming in a system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one video recorder and one video player with at least one of said detectors pre-programmed to detect distance information, consisting of the steps of:</p> <p>transmitting a plurality of units of television programming,</p> <p>causing a selected receiving station to record a selected television program unit,</p> <p>causing said selected receiving station to position the start of said program unit at the play head of a video player, and</p> <p>causing said video player thereafter to play and transmit at a selected time</p> <p>thereby to cause said selected receiving station to transmit said selected unit at said selected time.</p>

Application Claim 75	U.S. Pat. No. 5,109,414, Claim 21
<p>75. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, <u>said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image</u>, said method comprising the steps of:</p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image</u>, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</p> <p>transferring said downloadable processor instructions to a transmitter;</p>	<p>21. A method of communicating television programming in a system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one video recorder and one video player with at least one of said detectors pre-programmed to detect distance information, consisting of the steps of:</p> <p>transmitting a plurality of units of television programming,</p> <p>causing a selected receiving station to record a selected television program unit,</p> <p>causing said selected receiving station to position the start of said program unit at the play head of a video player, and</p> <p>causing said video player thereafter to play and transmit at a selected time</p> <p>thereby to cause said selected receiving station to transmit said selected unit at said selected time.</p>

<p>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</p> <p>transferring said at least one control signal to said transmitter; and</p> <p>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	
---	--

Application Claim 80	U.S. Pat. No. 5,109,414, Claim 21
<p>80. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u></p> <p>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</p> <p>transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>21. A method of communicating television programming in a system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one video recorder and one video player with at least one of said detectors pre-programmed to detect distance information, consisting of the steps of:</p> <p>transmitting a plurality of units of television programming,</p> <p>causing a selected receiving station to record a selected television program unit,</p> <p>causing said selected receiving station to position the start of said program unit at the play head of a video player, and</p> <p>causing said video player thereafter to play and transmit at a selected time</p> <p>thereby to cause said selected receiving station to transmit said selected unit at said selected time.</p>

Application Claim 84	U.S. Pat. No. 5,109,414, Claim 21
<p>84. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal,</p>	<p>21. A method of communicating television programming in a system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one video recorder and one video player</p>

<p>wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <p style="padding-left: 40px;">receiving video at a transmitter station;</p> <p style="padding-left: 40px;">delivering said video to a transmitter;</p> <p style="padding-left: 40px;">receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</p> <p style="padding-left: 40px;">transferring said first discrete signal to said transmitter; and</p> <p style="padding-left: 40px;">transmitting said video and said first discrete signal to said at least one receiver station.</p>	<p>with at least one of said detectors pre-programmed to detect distance information, consisting of the steps of:</p> <p style="padding-left: 40px;">transmitting a plurality of units of television programming,</p> <p style="padding-left: 40px;">causing a selected receiving station to record a selected television program unit,</p> <p style="padding-left: 40px;">causing said selected receiving station to position the start of said program unit at the play head of a video player, and</p> <p style="padding-left: 40px;">causing said video player thereafter to play and transmit at a selected time</p> <p style="padding-left: 40px;">thereby to cause said selected receiving station to transmit said selected unit at said selected time.</p>
---	---

Application Claim 93	U.S. Pat. No. 5,109,414, Claim 21
<p>93. A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <p style="padding-left: 40px;">receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal;</p> <p style="padding-left: 40px;">detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission;</p> <p style="padding-left: 40px;">passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor;</p> <p style="padding-left: 40px;"><u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p style="padding-left: 40px;">passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;</p> <p style="padding-left: 40px;">responding to said at least one processor instruction at said receiver station based on said step of passing</p>	<p>21. A method of communicating television programming in a system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one video recorder and one video player with at least one of said detectors pre-programmed to detect distance information, consisting of the steps of:</p> <p style="padding-left: 40px;">transmitting a plurality of units of television programming,</p> <p style="padding-left: 40px;">causing a selected receiving station to record a selected television program unit,</p> <p style="padding-left: 40px;">causing said selected receiving station to position the start of said program unit at the play head of a video player, and</p> <p style="padding-left: 40px;">causing said video player thereafter to play and transmit at a selected time</p> <p style="padding-left: 40px;">thereby to cause said selected receiving station to transmit said selected unit at said selected time.</p>

<p>said at least one processor instruction; <u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	
--	--

Application Claim 110	U.S. Pat. No. 5,109,414, Claim 21
<p>110. A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</p> <p><u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u></p> <p><u>transferring said at least said first discrete signal to at least one transmitter;</u></p> <p><u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u></p> <p><u>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</u></p>	<p>21. A method of communicating television programming in a system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one video recorder and one video player with at least one of said detectors pre-programmed to detect distance information, consisting of the steps of:</p> <p><u>transmitting a plurality of units of television programming,</u></p> <p><u>causing a selected receiving station to record a selected television program unit,</u></p> <p><u>causing said selected receiving station to position the start of said program unit at the play head of a video player, and</u></p> <p><u>causing said video player thereafter to play and transmit at a selected time</u></p> <p><u>thereby to cause said selected receiving station to transmit said selected unit at said selected time.</u></p>

Application Claim 116	U.S. Pat. No. 5,109,414, Claim 21
116. A method of delivering a video presentation	21. A method of communicating television

<p>at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</p> <p><u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u></p> <p>receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</p> <p>transferring said at least one control signal to said at least one origination transmitter before a specific time; and</p> <p>transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	<p>programming in a system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one video recorder and one video player with at least one of said detectors pre-programmed to detect distance information, consisting of the steps of:</p> <p>transmitting a plurality of units of television programming,</p> <p>causing a selected receiving station to record a selected television program unit,</p> <p>causing said selected receiving station to position the start of said program unit at the play head of a video player, and</p> <p>causing said video player thereafter to play and transmit at a selected time</p> <p>thereby to cause said selected receiving station to transmit said selected unit at said selected time.</p>
--	---

Application Claim 123	U.S. Pat. No. 5,109,414, Claim 21
<p>123. A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter</u></p>	<p>21. A method of communicating television programming in a system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one video recorder and one video player with at least one of said detectors pre-programmed to detect distance information, consisting of the steps of:</p> <p>transmitting a plurality of units of television programming,</p> <p>causing a selected receiving station to record a selected television program unit,</p> <p>causing said selected receiving station to position the start of said program unit at the play head of a video player, and</p> <p>causing said video player thereafter to play and</p>

<p><u>station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u> transferring said at least one instruct signal to at least one transmitter; receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	<p>transmit at a selected time thereby to cause said selected receiving station to transmit said selected unit at said selected time.</p>
--	--

Application Claim 142	U.S. Pat. No. 5,109,414, Claim 21
<p>142. A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of: receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal; detecting said at least a first discrete signal and said at least one control signal in said information transmission; passing said detected at least a first discrete signal to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> passing at least one processor instruction from or</p>	<p>21. A method of communicating television programming in a system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one video recorder and one video player with at least one of said detectors pre-programmed to detect distance information, consisting of the steps of: transmitting a plurality of units of television programming, causing a selected receiving station to record a selected television program unit, causing said selected receiving station to position the start of said program unit at the play head of a video player, and causing said video player thereafter to play and transmit at a selected time thereby to cause said selected receiving station to</p>

<p>within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing; responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; <u>generating only a portion of said video image based on said step of responding to said at least one processor instruction;</u> and <u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>transmit said selected unit at said selected time.</p>
---	---

Application Claim 143	U.S. Pat. No. 5,109,414, Claim 21
<p>143. A method of outputting a video presentation at a receiver station including: receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to processor instructions comprising said organized information, based on said step of organizing; generating a signal based on said processor instructions; and <u>outputting at least a portion of said video presentation based on said generated signal.</u></p>	<p>21. A method of communicating television programming in a system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one video recorder and one video player with at least one of said detectors pre-programmed to detect distance information, consisting of the steps of: transmitting a plurality of units of television programming, causing a selected receiving station to record a selected television program unit, causing said selected receiving station to position the start of said program unit at the play head of a video player, and causing said video player thereafter to play and transmit at a selected time thereby to cause said selected receiving station to transmit said selected unit at said selected time.</p>

Application Claim 152	U.S. Pat. No. 5,109,414, Claim 21
<p>152. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process <u>downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local</u></p>	<p>21. A method of communicating television programming in a system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one video recorder and one video player with at least one of said detectors pre-programmed to detect distance information, consisting of the steps of: transmitting a plurality of units of television</p>

<p><u>image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</u></p> <p>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p><u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>programming,</p> <p>causing a selected receiving station to record a selected television program unit,</p> <p>causing said selected receiving station to position the start of said program unit at the play head of a video player, and</p> <p>causing said video player thereafter to play and transmit at a selected time</p> <p>thereby to cause said selected receiving station to transmit said selected unit at said selected time.</p>
---	---

Application Claim 157	U.S. Pat. No. 5,109,414, Claim 21
<p>157. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p> <p>receiving, at said origination transmitter station, one</p>	<p>21. A method of communicating television programming in a system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one video recorder and one video player with at least one of said detectors pre-programmed to detect distance information, consisting of the steps of:</p> <p>transmitting a plurality of units of television programming,</p> <p>causing a selected receiving station to record a selected television program unit,</p> <p>causing said selected receiving station to position the start of said program unit at the play head of a video player, and</p> <p>causing said video player thereafter to play and transmit at a selected time</p> <p>thereby to cause said selected receiving station to</p>

or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and transmitting said one or more control signals from said origination transmitter before a specific time.	transmit said selected unit at said selected time.
--	--

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations in an operating environment of a receiver •transmitter station only.

Application Claim 162	U.S. Pat. No. 5,109,414, Claim 21
162. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals</u> , said method comprising the steps of: receiving a video image at a transmitter station; delivering said video image to a transmitter; <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> transferring said at least said first of said plurality of discrete signals to said transmitter; and transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.	21. A method of communicating television programming in a system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one video recorder and one video player with at least one of said detectors pre-programmed to detect distance information, consisting of the steps of: transmitting a plurality of units of television programming, causing a selected receiving station to record a selected television program unit, causing said selected receiving station to position the start of said program unit at the play head of a video player, and causing said video player thereafter to play and transmit at a selected time thereby to cause said selected receiving station to transmit said selected unit at said selected time.

Application Claim 167	U.S. Pat. No. 5,109,414, Claim 21
167. A method of outputting a video graphic presentation at a receiver station including:	21. A method of communicating television programming in a system that consists of a

<p><u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</u></p> <p>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal of said downloadable code;</p> <p>passing said at least a first discrete signal of said downloadable code to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u></p> <p><u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u></p> <p>wherein said method delivers said video graphic presentation.</p>	<p>transmission station and a plurality of receiving stations, each receiving station having at least one detector, one video recorder and one video player with at least one of said detectors pre-programmed to detect distance information, consisting of the steps of:</p> <p>transmitting a plurality of units of television programming,</p> <p>causing a selected receiving station to record a selected television program unit,</p> <p>causing said selected receiving station to position the start of said program unit at the play head of a video player, and</p> <p>causing said video player thereafter to play and transmit at a selected time</p> <p>thereby to cause said selected receiving station to transmit said selected unit at said selected time.</p>
--	--

Application Claim 171	U.S. Pat. No. 5,109,414, Claim 21
<p>171. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor</p>	<p>21. A method of communicating television programming in a system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one video recorder and one video player with at least one of said detectors pre-programmed to detect distance information, consisting of the steps of:</p> <p>transmitting a plurality of units of television</p>

instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;

transferring said at least one discrete signal to a transmitter;

receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said at least one discrete signal and said one or more control signals,

wherein said method delivers said video graphic presentation.

programming,

causing a selected receiving station to record a selected television program unit,

causing said selected receiving station to position the start of said program unit at the play head of a video player, and

causing said video player thereafter to play and transmit at a selected time

thereby to cause said selected receiving station to transmit said selected unit at said selected time.

Application Claim 175	U.S. Pat. No. 5,109,414, Claim 21
175. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of	21. A method of communicating television programming in a system that consists of a transmission station and a plurality of receiving

<p>said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</p> <p>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>stations, each receiving station having at least one detector, one video recorder and one video player with at least one of said detectors pre-programmed to detect distance information, consisting of the steps of:</p> <p>transmitting a plurality of units of television programming,</p> <p>causing a selected receiving station to record a selected television program unit,</p> <p>causing said selected receiving station to position the start of said program unit at the play head of a video player, and</p> <p>causing said video player thereafter to play and transmit at a selected time</p> <p>thereby to cause said selected receiving station to transmit said selected unit at said selected time.</p>
---	--

Application Claim 177	U.S. Pat. No. 5,109,414, Claim 21
177. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at	21. A method of communicating television programming in a system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one

<p>least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>transferring said one or more instruct signals to said transmitter; and</p> <p>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>detector, one video recorder and one video player with at least one of said detectors pre-programmed to detect distance information, consisting of the steps of:</p> <p>transmitting a plurality of units of television programming,</p> <p>causing a selected receiving station to record a selected television program unit,</p> <p>causing said selected receiving station to position the start of said program unit at the play head of a video player, and</p> <p>causing said video player thereafter to play and transmit at a selected time</p> <p>thereby to cause said selected receiving station to transmit said selected unit at said selected time.</p>
--	---

Application Claim 179	U.S. Pat. No. 5,109,414, Claim 21
<p>179. A method of outputting a video graphic presentation at a receiver station including:</p> <p>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</p> <p>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of</p>	<p>21. A method of communicating television programming in a system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one video recorder and one video player with at least one of said detectors pre-programmed to detect distance information, consisting of the steps of:</p> <p>transmitting a plurality of units of television programming,</p> <p>causing a selected receiving station to record a selected television program unit,</p>

<p>video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal;</p> <p>passing said at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u></p> <p><u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u></p> <p>wherein said method delivers said video graphic presentation.</p>	<p>causing said selected receiving station to position the start of said program unit at the play head of a video player, and</p> <p>causing said video player thereafter to play and transmit at a selected time</p> <p>thereby to cause said selected receiving station to transmit said selected unit at said selected time.</p>
--	---

Application Claim 56	U.S. Pat. No. 5,109,414, Claim 22
<p>56. A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying <u>a video presentation comprising a locally generated image and an image received from a remote video source</u>, said method comprising the steps of:</p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p>and</p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>22. A method of communicating television programming in a multichannel television system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one video recorder and one video layer with at least one of said detectors pre-programmed to detect distance information, consisting of the steps of:</p> <p>transmitting a plurality of units of television programming,</p> <p>causing a selected receiving station to record a selected television program unit,</p> <p>causing said selected receiving station to position the start of said program unit at the play head of a video player, and</p> <p>causing said video player thereafter to play and transmit at a selected time</p> <p>thereby to cause said selected receiving station to transmit said selected unit at said selected time.</p>

Application Claim 75	U.S. Pat. No. 5,109,414, Claim 22
<p>75. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, <u>said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image</u>, said method comprising the steps of:</p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image</u>, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</p> <p>transferring said downloadable processor instructions to a transmitter;</p>	<p>22. A method of communicating television programming in a multichannel television system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one video recorder and one video layer with at least one of said detectors pre-programmed to detect distance information, consisting of the steps of:</p> <p>transmitting a plurality of units of television programming,</p> <p>causing a selected receiving station to record a selected television program unit,</p> <p>causing said selected receiving station to position the start of said program unit at the play head of a video player, and</p> <p>causing said video player thereafter to play and transmit at a selected time</p> <p>thereby to cause said selected receiving station to transmit said selected unit at said selected time.</p>

<p>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</p> <p>transferring said at least one control signal to said transmitter; and</p> <p>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	
---	--

Application Claim 80	U.S. Pat. No. 5,109,414, Claim 22
<p>80. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u></p> <p>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</p> <p>transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>22. A method of communicating television programming in a multichannel television system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one video recorder and one video layer with at least one of said detectors pre-programmed to detect distance information, consisting of the steps of:</p> <p>transmitting a plurality of units of television programming,</p> <p>causing a selected receiving station to record a selected television program unit,</p> <p>causing said selected receiving station to position the start of said program unit at the play head of a video player, and</p> <p>causing said video player thereafter to play and transmit at a selected time</p> <p>thereby to cause said selected receiving station to transmit said selected unit at said selected time.</p>

Application Claim 84	U.S. Pat. No. 5,109,414, Claim 22
<p>84. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal,</p>	<p>22. A method of communicating television programming in a multichannel television system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one video recorder and one video</p>

<p>wherein at least one processor instruction comprises <u>information content of separate ones of a plurality of discrete signals</u> and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving video at a transmitter station; delivering said video to a transmitter; <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and transmitting said video and said first discrete signal to said at least one receiver station. 	<p>layer with at least one of said detectors pre-programmed to detect distance information, consisting of the steps of:</p> <ul style="list-style-type: none"> transmitting a plurality of units of television programming, causing a selected receiving station to record a selected television program unit, causing said selected receiving station to position the start of said program unit at the play head of a video player, and causing said video player thereafter to play and transmit at a selected time thereby to cause said selected receiving station to transmit said selected unit at said selected time.
--	--

Application Claim 93	U.S. Pat. No. 5,109,414, Claim 22
<p>93. A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal; detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission; passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor; <u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing; responding to said at least one processor instruction at said receiver station based on said step of passing 	<p>22. A method of communicating television programming in a multichannel television system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one video recorder and one video layer with at least one of said detectors pre-programmed to detect distance information, consisting of the steps of:</p> <ul style="list-style-type: none"> transmitting a plurality of units of television programming, causing a selected receiving station to record a selected television program unit, causing said selected receiving station to position the start of said program unit at the play head of a video player, and causing said video player thereafter to play and transmit at a selected time thereby to cause said selected receiving station to transmit said selected unit at said selected time.

<p>said at least one processor instruction; <u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	
--	--

Application Claim 110	U.S. Pat. No. 5,109,414, Claim 22
<p>110. A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</p> <p><u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u></p> <p>transferring said at least said first discrete signal to at least one transmitter;</p> <p><u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u></p> <p>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>22. A method of communicating television programming in a multichannel television system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one video recorder and one video layer with at least one of said detectors pre-programmed to detect distance information, consisting of the steps of:</p> <p>transmitting a plurality of units of television programming,</p> <p>causing a selected receiving station to record a selected television program unit,</p> <p>causing said selected receiving station to position the start of said program unit at the play head of a video player, and</p> <p>causing said video player thereafter to play and transmit at a selected time</p> <p>thereby to cause said selected receiving station to transmit said selected unit at said selected time.</p>

Application Claim 116	U.S. Pat. No. 5,109,414, Claim 22
116. A method of delivering a video presentation	22. A method of communicating television

<p>at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, <u>wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction</u>, said method comprising the steps of:</p> <p style="padding-left: 2em;"><u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u></p> <p style="padding-left: 2em;">receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</p> <p style="padding-left: 2em;">transferring said at least one control signal to said at least one origination transmitter before a specific time; and</p> <p style="padding-left: 2em;">transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	<p>programming in a multichannel television system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one video recorder and one video layer with at least one of said detectors pre-programmed to detect distance information, consisting of the steps of:</p> <p style="padding-left: 2em;">transmitting a plurality of units of television programming,</p> <p style="padding-left: 2em;">causing a selected receiving station to record a selected television program unit,</p> <p style="padding-left: 2em;">causing said selected receiving station to position the start of said program unit at the play head of a video player, and</p> <p style="padding-left: 2em;">causing said video player thereafter to play and transmit at a selected time</p> <p style="padding-left: 2em;">thereby to cause said selected receiving station to transmit said selected unit at said selected time.</p>
---	---

Application Claim 123	U.S. Pat. No. 5,109,414, Claim 22
<p>123. A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</p> <p style="padding-left: 2em;"><u>receiving at at least one of said first remote transmitter station and a second remote transmitter</u></p>	<p>22. A method of communicating television programming in a multichannel television system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one video recorder and one video layer with at least one of said detectors pre-programmed to detect distance information, consisting of the steps of:</p> <p style="padding-left: 2em;">transmitting a plurality of units of television programming,</p> <p style="padding-left: 2em;">causing a selected receiving station to record a selected television program unit,</p> <p style="padding-left: 2em;">causing said selected receiving station to position the start of said program unit at the play head of a video player, and</p>

<p><u>station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p>transferring said at least one instruct signal to at least one transmitter;</p> <p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and</u></p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	<p>causing said video player thereafter to play and transmit at a selected time</p> <p>thereby to cause said selected receiving station to transmit said selected unit at said selected time.</p>
---	---

Application Claim 142	U.S. Pat. No. 5,109,414, Claim 22
<p>142. A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or</p>	<p>22. A method of communicating television programming in a multichannel television system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one video recorder and one video layer with at least one of said detectors pre-programmed to detect distance information, consisting of the steps of:</p> <p>transmitting a plurality of units of television programming,</p> <p>causing a selected receiving station to record a selected television program unit,</p> <p>causing said selected receiving station to position the start of said program unit at the play head of a video player, and</p> <p>causing said video player thereafter to play and transmit at a selected time</p>

<p>within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing; responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; <u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>thereby to cause said selected receiving station to transmit said selected unit at said selected time.</p>
---	---

Application Claim 143	U.S. Pat. No. 5,109,414, Claim 22
<p>143. A method of outputting a video presentation at a receiver station including: receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to processor instructions comprising said organized information, based on said step of organizing; generating a signal based on said processor instructions; and <u>outputting at least a portion of said video presentation based on said generated signal.</u></p>	<p>22. A method of communicating television programming in a multichannel television system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one video recorder and one video layer with at least one of said detectors pre-programmed to detect distance information, consisting of the steps of: transmitting a plurality of units of television programming, causing a selected receiving station to record a selected television program unit, causing said selected receiving station to position the start of said program unit at the play head of a video player, and causing said video player thereafter to play and transmit at a selected time thereby to cause said selected receiving station to transmit said selected unit at said selected time.</p>

Application Claim 152	U.S. Pat. No. 5,109,414, Claim 22
<p>152. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process <u>downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local</u></p>	<p>22. A method of communicating television programming in a multichannel television system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one video recorder and one video layer with at least one of said detectors pre-programmed to detect distance information, consisting of the steps of:</p>

<p><u>image of said video presentation</u> and have a target processor to process data, <u>said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station</u>, said method comprising the steps of:</p> <p>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p><u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>transmitting a plurality of units of television programming,</p> <p>causing a selected receiving station to record a selected television program unit,</p> <p>causing said selected receiving station to position the start of said program unit at the play head of a video player, and</p> <p>causing said video player thereafter to play and transmit at a selected time</p> <p>thereby to cause said selected receiving station to transmit said selected unit at said selected time.</p>
--	---

Application Claim 157	U.S. Pat. No. 5,109,414, Claim 22
<p>157. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p> <p>receiving, at said origination transmitter station, one</p>	<p>22. A method of communicating television programming in a multichannel television system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one video recorder and one video layer with at least one of said detectors pre-programmed to detect distance information, consisting of the steps of:</p> <p>transmitting a plurality of units of television programming,</p> <p>causing a selected receiving station to record a selected television program unit,</p> <p>causing said selected receiving station to position the start of said program unit at the play head of a video player, and</p> <p>causing said video player thereafter to play and transmit at a selected time</p>

or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and transmitting said one or more control signals from said origination transmitter before a specific time.	thereby to cause said selected receiving station to transmit said selected unit at said selected time.
--	--

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations in an operating environment of a receiver •transmitter station only.

Application Claim 162	U.S. Pat. No. 5,109,414, Claim 22
162. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals</u> , said method comprising the steps of: receiving a video image at a transmitter station; delivering said video image to a transmitter; <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> transferring said at least said first of said plurality of discrete signals to said transmitter; and transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.	22. A method of communicating television programming in a multichannel television system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one video recorder and one video layer with at least one of said detectors pre-programmed to detect distance information, consisting of the steps of: transmitting a plurality of units of television programming, causing a selected receiving station to record a selected television program unit, causing said selected receiving station to position the start of said program unit at the play head of a video player, and causing said video player thereafter to play and transmit at a selected time thereby to cause said selected receiving station to transmit said selected unit at said selected time.

Application Claim 167	U.S. Pat. No. 5,109,414, Claim 22
167. A method of outputting a video graphic presentation at a receiver station including:	22. A method of communicating television programming in a multichannel television system that

<p><u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</u></p> <p>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal of said downloadable code;</p> <p>passing said at least a first discrete signal of said downloadable code to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u></p> <p><u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u></p> <p>wherein said method delivers said video graphic presentation.</p>	<p>consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one video recorder and one video layer with at least one of said detectors pre-programmed to detect distance information, consisting of the steps of:</p> <p>transmitting a plurality of units of television programming,</p> <p>causing a selected receiving station to record a selected television program unit,</p> <p>causing said selected receiving station to position the start of said program unit at the play head of a video player, and</p> <p>causing said video player thereafter to play and transmit at a selected time</p> <p>thereby to cause said selected receiving station to transmit said selected unit at said selected time.</p>
--	---

Application Claim 171	U.S. Pat. No. 5,109,414, Claim 22
<p>171. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor</p>	<p>22. A method of communicating television programming in a multichannel television system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one video recorder and one video layer with at least one of said detectors pre-programmed to detect distance information, consisting of the steps of:</p>

<p><u>instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:</u></p> <p style="padding-left: 20px;"><u>receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</u></p> <p style="padding-left: 20px;">transferring said at least one discrete signal to a transmitter;</p> <p style="padding-left: 20px;"><u>receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;</u></p> <p style="padding-left: 20px;">transferring said one or more control signals to said transmitter; and</p> <p style="padding-left: 20px;">transmitting a transmission comprising said at least one discrete signal and said one or more control signals,</p> <p style="padding-left: 20px;">wherein said method delivers said video graphic presentation.</p>	<p>transmitting a plurality of units of television programming,</p> <p style="padding-left: 20px;">causing a selected receiving station to record a selected television program unit,</p> <p style="padding-left: 20px;">causing said selected receiving station to position the start of said program unit at the play head of a video player, and</p> <p style="padding-left: 20px;">causing said video player thereafter to play and transmit at a selected time</p> <p style="padding-left: 20px;">thereby to cause said selected receiving station to transmit said selected unit at said selected time.</p>
--	---

Application Claim 175	U.S. Pat. No. 5,109,414, Claim 22
175. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of	22. A method of communicating television programming in a multichannel television system that consists of a transmission station and a plurality of

<p>said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</p> <p>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>receiving stations, each receiving station having at least one detector, one video recorder and one video layer with at least one of said detectors pre-programmed to detect distance information, consisting of the steps of:</p> <p>transmitting a plurality of units of television programming,</p> <p>causing a selected receiving station to record a selected television program unit,</p> <p>causing said selected receiving station to position the start of said program unit at the play head of a video player, and</p> <p>causing said video player thereafter to play and transmit at a selected time</p> <p>thereby to cause said selected receiving station to transmit said selected unit at said selected time.</p>
---	---

Application Claim 177	U.S. Pat. No. 5,109,414, Claim 22
177. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at	22. A method of communicating television programming in a multichannel television system that consists of a transmission station and a plurality of receiving stations, each receiving station having at

<p>least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>transferring said one or more instruct signals to said transmitter; and</p> <p>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>least one detector, one video recorder and one video layer with at least one of said detectors pre-programmed to detect distance information, consisting of the steps of:</p> <p>transmitting a plurality of units of television programming,</p> <p>causing a selected receiving station to record a selected television program unit,</p> <p>causing said selected receiving station to position the start of said program unit at the play head of a video player, and</p> <p>causing said video player thereafter to play and transmit at a selected time</p> <p>thereby to cause said selected receiving station to transmit said selected unit at said selected time.</p>
--	--

Application Claim 179	U.S. Pat. No. 5,109,414, Claim 22
<p>179. A method of outputting a video graphic presentation at a receiver station including:</p> <p>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</p> <p>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of</p>	<p>22. A method of communicating television programming in a multichannel television system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one video recorder and one video layer with at least one of said detectors pre-programmed to detect distance information, consisting of the steps of:</p> <p>transmitting a plurality of units of television programming,</p> <p>causing a selected receiving station to record a</p>

video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;
detecting said at least a first discrete signal;
passing said at least a first discrete signal to at least one processor;
organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;
responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;
passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and
displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,
wherein said method delivers said video graphic presentation.

selected television program unit,
causing said selected receiving station to position the start of said program unit at the play head of a video player, and
causing said video player thereafter to play and transmit at a selected time
thereby to cause said selected receiving station to transmit said selected unit at said selected time.

Application Claim 56	U.S. Pat. No. 5,109,414, Claim 23
<p>56. A method for receiving and processing data for use with an interactive video apparatus, <u>said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source</u>, said method comprising the steps of:</p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p>and</p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>23. A method of inputting data in a system that consists of a first input means, at least one intermediate input means, and a plurality of processors consisting of the steps of:</p> <p>transmitting a plurality of data units,</p> <p>causing memory means associated with a selected intermediate input means to record a selected data unit, and</p> <p>causing said memory means to transmit selected information of said selected data unit at a selected time,</p> <p>thereby to cause said intermediate input means to input data of said selected data unit to at least one selected processor at said selected time and cause said processor to process said input data.</p>

Application Claim 75	U.S. Pat. No. 5,109,414, Claim 23
<p>75. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, <u>said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image</u>, said method comprising the steps of:</p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</u></p> <p>transferring said downloadable processor instructions to a transmitter;</p>	<p>23. A method of inputting data in a system that consists of a first input means, at least one intermediate input means, and a plurality of processors consisting of the steps of:</p> <p>transmitting a plurality of data units,</p> <p>causing memory means associated with a selected intermediate input means to record a selected data unit, and</p> <p>causing said memory means to transmit selected information of said selected data unit at a selected time,</p> <p>thereby to cause said intermediate input means to input data of said selected data unit to at least one selected processor at said selected time and cause said processor to process said input data.</p>

<p><u>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</u> transferring said at least one control signal to said transmitter; and transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	
--	--

Application Claim 80	U.S. Pat. No. 5,109,414, Claim 23
<p>80. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</p> <p><u>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>23. A method of inputting data in a system that consists of a first input means, at least one intermediate input means, and a plurality of processors consisting of the steps of:</p> <p>transmitting a plurality of data units, causing memory means associated with a selected intermediate input means to record a selected data unit, and causing said memory means to transmit selected information of said selected data unit at a selected time, thereby to cause said intermediate input means to input data of said selected data unit to at least one selected processor at said selected time and cause said processor to process said input data.</p>

Application Claim 84	U.S. Pat. No. 5,109,414, Claim 23
<p>84. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal,</p>	<p>23. A method of inputting data in a system that consists of a first input means, at least one intermediate input means, and a plurality of processors consisting of the steps of:</p> <p>transmitting a plurality of data units,</p>

<p>wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <p style="padding-left: 20px;"><u>receiving video at a transmitter station;</u> <u>delivering said video to a transmitter;</u> <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and <u>transmitting said video and said first discrete signal to said at least one receiver station.</u></p>	<p>causing memory means associated with a selected intermediate input means to record a selected data unit, and</p> <p style="padding-left: 20px;">causing said memory means to transmit selected information of said selected data unit at a selected time,</p> <p style="padding-left: 20px;">thereby to cause said intermediate input means to input data of said selected data unit to at least one selected processor at said selected time and cause said processor to process said input data.</p>
---	---

Application Claim 93	U.S. Pat. No. 5,109,414, Claim 23
<p>93. A method of outputting a video presentation at a receiver station, <u>said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image</u>, said method comprising the steps of:</p> <p style="padding-left: 20px;">receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal;</p> <p style="padding-left: 20px;">detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission;</p> <p style="padding-left: 20px;">passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor;</p> <p style="padding-left: 20px;"><u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p style="padding-left: 20px;">passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p style="padding-left: 20px;">responding to said at least one processor instruction at said receiver station based on said step of passing</p>	<p>23. A method of inputting data in a system that consists of a first input means, at least one intermediate input means, and a plurality of processors consisting of the steps of:</p> <p style="padding-left: 20px;">transmitting a plurality of data units,</p> <p style="padding-left: 20px;">causing memory means associated with a selected intermediate input means to record a selected data unit, and</p> <p style="padding-left: 20px;">causing said memory means to transmit selected information of said selected data unit at a selected time,</p> <p style="padding-left: 20px;">thereby to cause said intermediate input means to input data of said selected data unit to at least one selected processor at said selected time and cause said processor to process said input data.</p>

<p>said at least one processor instruction; <u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	
--	--

Application Claim 110	U.S. Pat. No. 5,109,414, Claim 23
<p>110. A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of: <u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u> <u>transferring said at least said first discrete signal to at least one transmitter;</u> <u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u> <u>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</u></p>	<p>23. A method of inputting data in a system that consists of a first input means, at least one intermediate input means, and a plurality of processors consisting of the steps of: transmitting a plurality of data units, causing memory means associated with a selected intermediate input means to record a selected data unit, and causing said memory means to transmit selected information of said selected data unit at a selected time, thereby to cause said intermediate input means to input data of said selected data unit to at least one selected processor at said selected time and cause said processor to process said input data.</p>

Application Claim 116	U.S. Pat. No. 5,109,414, Claim 23
116. A method of delivering a video presentation	23. A method of inputting data in a system that

<p>at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, <u>wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction</u>, said method comprising the steps of:</p> <p style="padding-left: 20px;"><u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u></p> <p style="padding-left: 20px;">receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</p> <p style="padding-left: 20px;">transferring said at least one control signal to said at least one origination transmitter before a specific time; and</p> <p style="padding-left: 20px;">transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	<p>consists of a first input means, at least one intermediate input means, and a plurality of processors consisting of the steps of:</p> <p style="padding-left: 20px;">transmitting a plurality of data units,</p> <p style="padding-left: 20px;">causing memory means associated with a selected intermediate input means to record a selected data unit, and</p> <p style="padding-left: 20px;">causing said memory means to transmit selected information of said selected data unit at a selected time,</p> <p style="padding-left: 20px;">thereby to cause said intermediate input means to input data of said selected data unit to at least one selected processor at said selected time and cause said processor to process said input data.</p>
---	---

Application Claim 123	U.S. Pat. No. 5,109,414, Claim 23
<p>123. A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, <u>wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station</u>, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device; said method comprising the steps of:</p> <p style="padding-left: 20px;"><u>receiving at at least one of said first remote transmitter station and a second remote transmitter</u></p>	<p>23. A method of inputting data in a system that consists of a first input means, at least one intermediate input means, and a plurality of processors consisting of the steps of:</p> <p style="padding-left: 20px;">transmitting a plurality of data units,</p> <p style="padding-left: 20px;">causing memory means associated with a selected intermediate input means to record a selected data unit, and</p> <p style="padding-left: 20px;">causing said memory means to transmit selected information of said selected data unit at a selected time,</p> <p style="padding-left: 20px;">thereby to cause said intermediate input means to input data of said selected data unit to at least one selected processor at said selected time and cause said processor to process said input data.</p>

<p><u>station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p>transferring said at least one instruct signal to at least one transmitter;</p> <p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and</u></p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	
---	--

Application Claim 142	U.S. Pat. No. 5,109,414, Claim 23
<p>142. A method of outputting a video presentation at a receiver station, <u>said video presentation including a video image</u>, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or</p>	<p>23. A method of inputting data in a system that consists of a first input means, at least one intermediate input means, and a plurality of processors consisting of the steps of:</p> <p>transmitting a plurality of data units,</p> <p>causing memory means associated with a selected intermediate input means to record a selected data unit, and</p> <p>causing said memory means to transmit selected information of said selected data unit at a selected time,</p> <p>thereby to cause said intermediate input means to input data of said selected data unit to at least one selected processor at said selected time and cause said processor to process said input data.</p>

<p>within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; <u>generating only a portion of said video image based on said step of responding to said at least one processor instruction;</u> and <u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	
--	--

Application Claim 143	U.S. Pat. No. 5,109,414, Claim 23
<p>143. A method of outputting a video presentation at a receiver station including: <u>receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal;</u> <u>passing said received video image to an output device for delivery to a user;</u> detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to <u>processor instructions comprising said organized information,</u> based on said step of organizing; generating a signal based on said processor instructions; and <u>outputting at least a portion of said video presentation based on said generated signal.</u></p>	<p>23. A method of inputting data in a system that consists of a first input means, at least one intermediate input means, and a plurality of processors consisting of the steps of: transmitting a plurality of data units, causing memory means associated with a selected intermediate input means to record a selected data unit, and causing said memory means to transmit selected information of said selected data unit at a selected time, thereby to cause said intermediate input means to input data of said selected data unit to at least one selected processor at said selected time and cause said processor to process said input data.</p>

Application Claim 152	U.S. Pat. No. 5,109,414, Claim 23
<p>152. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process <u>downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local</u></p>	<p>23. A method of inputting data in a system that consists of a first input means, at least one intermediate input means, and a plurality of processors consisting of the steps of: transmitting a plurality of data units, causing memory means associated with a selected intermediate input means to record a selected data unit, and</p>

<p><u>image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</u></p> <p>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein <u>said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>causing said memory means to transmit selected information of said selected data unit at a selected time,</p> <p>thereby to cause said intermediate input means to input data of said selected data unit to at least one selected processor at said selected time and cause said processor to process said input data.</p>
---	---

Application Claim 157	U.S. Pat. No. 5,109,414, Claim 23
<p>157. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p><u>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</u></p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p> <p>receiving, at said origination transmitter station, one</p>	<p>23. A method of inputting data in a system that consists of a first input means, at least one intermediate input means, and a plurality of processors consisting of the steps of:</p> <p>transmitting a plurality of data units,</p> <p>causing memory means associated with a selected intermediate input means to record a selected data unit, and</p> <p>causing said memory means to transmit selected information of said selected data unit at a selected time,</p> <p>thereby to cause said intermediate input means to input data of said selected data unit to at least one selected processor at said selected time and cause said processor to process said input data.</p>

<p>or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</p> <p>transmitting said one or more control signals from said origination transmitter before a specific time.</p>	
---	--

Application Claim 162	U.S. Pat. No. 5,109,414, Claim 23
<p>162. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals</u>, said method comprising the steps of:</p> <p><u>receiving a video image at a transmitter station;</u></p> <p><u>delivering said video image to a transmitter;</u></p> <p><u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u></p> <p>transferring said at least said first of said plurality of discrete signals to said transmitter; and</p> <p><u>transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</u></p>	<p>23. A method of inputting data in a system that consists of a first input means, at least one intermediate input means, and a plurality of processors consisting of the steps of:</p> <p>transmitting a plurality of data units,</p> <p>causing memory means associated with a selected intermediate input means to record a selected data unit, and</p> <p>causing said memory means to transmit selected information of said selected data unit at a selected time,</p> <p>thereby to cause said intermediate input means to input data of said selected data unit to at least one selected processor at said selected time and cause said processor to process said input data.</p>

Application Claim 167	U.S. Pat. No. 5,109,414, Claim 23
<p>167. A method of outputting a video graphic presentation at a receiver station including:</p> <p><u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one</u></p>	<p>23. A method of inputting data in a system that consists of a first input means, at least one intermediate input means, and a plurality of processors consisting of the steps of:</p> <p>transmitting a plurality of data units,</p> <p>causing memory means associated with a selected intermediate input means to record a selected data</p>

<p><u>graphic image;</u> <u>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal of said downloadable code;</u> <u>passing said at least a first discrete signal of said downloadable code to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>unit, and causing said memory means to transmit selected information of said selected data unit at a selected time, thereby to cause said intermediate input means to input data of said selected data unit to at least one selected processor at said selected time and cause said processor to process said input data.</p>
---	--

Application Claim 171	U.S. Pat. No. 5,109,414, Claim 23
<p>171. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, <u>wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic</u></p>	<p>23. A method of inputting data in a system that consists of a first input means, at least one intermediate input means, and a plurality of processors consisting of the steps of: transmitting a plurality of data units, causing memory means associated with a selected intermediate input means to record a selected data unit, and causing said memory means to transmit selected information of said selected data unit at a selected time, thereby to cause said intermediate input means to input data of said selected data unit to at least one</p>

<p><u>image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:</u></p> <p style="padding-left: 2em;"><u>receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</u></p> <p style="padding-left: 2em;"><u>transferring said at least one discrete signal to a transmitter;</u></p> <p style="padding-left: 2em;"><u>receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;</u></p> <p style="padding-left: 2em;"><u>transferring said one or more control signals to said transmitter; and</u></p> <p style="padding-left: 2em;"><u>transmitting a transmission comprising said at least one discrete signal and said one or more control signals,</u></p> <p style="padding-left: 2em;"><u>wherein said method delivers said video graphic presentation.</u></p>	<p>selected processor at said selected time and cause said processor to process said input data.</p>
--	--

Application Claim 175	U.S. Pat. No. 5,109,414, Claim 23
<p>175. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</p>	<p>23. A method of inputting data in a system that consists of a first input means, at least one intermediate input means, and a plurality of processors consisting of the steps of:</p> <p style="padding-left: 2em;">transmitting a plurality of data units,</p> <p style="padding-left: 2em;">causing memory means associated with a selected intermediate input means to record a selected data unit, and</p>

receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;

delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;

receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and

transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,

wherein said method delivers said video graphic presentation.

causing said memory means to transmit selected information of said selected data unit at a selected time,

thereby to cause said intermediate input means to input data of said selected data unit to at least one selected processor at said selected time and cause said processor to process said input data.

Application Claim 177	U.S. Pat. No. 5,109,414, Claim 23
<p>177. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p><u>receiving a first completed full-screen video graphic</u></p>	<p>23. A method of inputting data in a system that consists of a first input means, at least one intermediate input means, and a plurality of processors consisting of the steps of:</p> <p>transmitting a plurality of data units,</p> <p>causing memory means associated with a selected intermediate input means to record a selected data unit, and</p> <p>causing said memory means to transmit selected</p>

<p><u>image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</u></p> <p><u>delivering said received first completed full-screen video graphic image to a transmitter;</u></p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>transferring said one or more instruct signals to said transmitter; and</u></p> <p><u>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>information of said selected data unit at a selected time,</p> <p>thereby to cause said intermediate input means to input data of said selected data unit to at least one selected processor at said selected time and cause said processor to process said input data.</p>
---	--

Application Claim 179	U.S. Pat. No. 5,109,414, Claim 23
<p>179. A method of outputting a video graphic presentation at a receiver station including:</p> <p>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</p> <p><u>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</u></p> <p><u>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u></p> <p>detecting said at least a first discrete signal;</p> <p>passing said at least a first discrete signal to at least</p>	<p>23. A method of inputting data in a system that consists of a first input means, at least one intermediate input means, and a plurality of processors consisting of the steps of:</p> <p>transmitting a plurality of data units,</p> <p>causing memory means associated with a selected intermediate input means to record a selected data unit, and</p> <p>causing said memory means to transmit selected information of said selected data unit at a selected time,</p> <p>thereby to cause said intermediate input means to input data of said selected data unit to at least one selected processor at said selected time and cause said processor to process said input data.</p>

one processor;

organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;

responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;

passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and

displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,

wherein said method delivers said video graphic presentation.

Application Claim 56	U.S. Pat. No. 5,109,414, Claim 24
<p>56. A method for receiving and processing data for use with an interactive video apparatus, <u>said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source</u>, said method comprising the steps of:</p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p>and</p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>24. A method of inputting data in a system that consists of a first input means, at least one intermediate input means, and a plurality of processors consisting of the steps of:</p> <p>transmitting a plurality of data units,</p> <p>causing recorder means associated with a selected intermediate input means to record a selected data unit, and</p> <p>causing a switch associated with said intermediate input means to connect the output of a player associated with said recorder to at least one selected processor at a selected time,</p> <p>thereby to enable said intermediate input means to input data of said selected data unit to said selected processor and cause said processor to process said input data.</p>

Application Claim 75	U.S. Pat. No. 5,109,414, Claim 24
<p>75. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, <u>said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image</u>, said method comprising the steps of:</p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</u></p> <p><u>transferring said downloadable processor</u></p>	<p>24. A method of inputting data in a system that consists of a first input means, at least one intermediate input means, and a plurality of processors consisting of the steps of:</p> <p>transmitting a plurality of data units,</p> <p>causing recorder means associated with a selected intermediate input means to record a selected data unit, and</p> <p>causing a switch associated with said intermediate input means to connect the output of a player associated with said recorder to at least one selected processor at a selected time,</p> <p>thereby to enable said intermediate input means to input data of said selected data unit to said selected processor and cause said processor to process said input data.</p>

<p>instructions to a transmitter;</p> <p><u>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</u></p> <p>transferring said at least one control signal to said transmitter; and</p> <p>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	
--	--

Application Claim 80	U.S. Pat. No. 5,109,414, Claim 24
<p>80. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</p> <p><u>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</u></p> <p><u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u></p> <p>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</p> <p>transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>24. A method of inputting data in a system that consists of a first input means, at least one intermediate input means, and a plurality of processors consisting of the steps of:</p> <p>transmitting a plurality of data units,</p> <p>causing recorder means associated with a selected intermediate input means to record a selected data unit, and</p> <p>causing a switch associated with said intermediate input means to connect the output of a player associated with said recorder to at least one selected processor at a selected time,</p> <p>thereby to enable said intermediate input means to input data of said selected data unit to said selected processor and cause said processor to process said input data.</p>

Application Claim 84	U.S. Pat. No. 5,109,414, Claim 24
<p>84. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is</p>	<p>24. A method of inputting data in a system that consists of a first input means, at least one intermediate input means, and a plurality of processors consisting of the steps of:</p>

<p>adapted to detect the presence of at least one signal, <u>wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals</u> and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <p style="padding-left: 40px;"><u>receiving video at a transmitter station;</u> <u>delivering said video to a transmitter;</u> <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and <u>transmitting said video and said first discrete signal to said at least one receiver station.</u></p>	<p>transmitting a plurality of data units, causing recorder means associated with a selected intermediate input means to record a selected data unit, and causing a switch associated with said intermediate input means to connect the output of a player associated with said recorder to at least one selected processor at a selected time, thereby to enable said intermediate input means to input data of said selected data unit to said selected processor and cause said processor to process said input data.</p>
---	---

Application Claim 93	U.S. Pat. No. 5,109,414, Claim 24
<p>93. A method of outputting a video presentation at a receiver station, <u>said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image</u>, said method comprising the steps of:</p> <p style="padding-left: 40px;">receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal; detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission; passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor; <u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> responding to said at least one processor instruction</p>	<p>24. A method of inputting data in a system that consists of a first input means, at least one intermediate input means, and a plurality of processors consisting of the steps of:</p> <p style="padding-left: 40px;">transmitting a plurality of data units, causing recorder means associated with a selected intermediate input means to record a selected data unit, and causing a switch associated with said intermediate input means to connect the output of a player associated with said recorder to at least one selected processor at a selected time, thereby to enable said intermediate input means to input data of said selected data unit to said selected processor and cause said processor to process said input data.</p>

<p>at said receiver station based on said step of passing said at least one processor instruction; <u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	
---	--

Application Claim 110	U.S. Pat. No. 5,109,414, Claim 24
<p>110. A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of: <u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u> <u>transferring said at least said first discrete signal to at least one transmitter;</u> <u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u> <u>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</u></p>	<p>24. A method of inputting data in a system that consists of a first input means, at least one intermediate input means, and a plurality of processors consisting of the steps of: transmitting a plurality of data units, causing recorder means associated with a selected intermediate input means to record a selected data unit, and causing a switch associated with said intermediate input means to connect the output of a player associated with said recorder to at least one selected processor at a selected time, thereby to enable said intermediate input means to input data of said selected data unit to said selected processor and cause said processor to process said input data.</p>

Application Claim 116	U.S. Pat. No. 5,109,414, Claim 24
-----------------------	-----------------------------------

<p>116. A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, <u>wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction</u>, said method comprising the steps of:</p> <p style="padding-left: 20px;"><u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u></p> <p style="padding-left: 20px;">receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</p> <p style="padding-left: 20px;">transferring said at least one control signal to said at least one origination transmitter before a specific time; and</p> <p style="padding-left: 20px;">transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	<p>24. A method of inputting data in a system that consists of a first input means, at least one intermediate input means, and a plurality of processors consisting of the steps of:</p> <p style="padding-left: 20px;">transmitting a plurality of data units,</p> <p style="padding-left: 20px;">causing recorder means associated with a selected intermediate input means to record a selected data unit, and</p> <p style="padding-left: 20px;">causing a switch associated with said intermediate input means to connect the output of a player associated with said recorder to at least one selected processor at a selected time,</p> <p style="padding-left: 20px;">thereby to enable said intermediate input means to input data of said selected data unit to said selected processor and cause said processor to process said input data.</p>
--	--

Application Claim 123	U.S. Pat. No. 5,109,414, Claim 24
<p>123. A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, <u>wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station</u>, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</p> <p style="padding-left: 20px;"><u>receiving at at least one of said first remote</u></p>	<p>24. A method of inputting data in a system that consists of a first input means, at least one intermediate input means, and a plurality of processors consisting of the steps of:</p> <p style="padding-left: 20px;">transmitting a plurality of data units,</p> <p style="padding-left: 20px;">causing recorder means associated with a selected intermediate input means to record a selected data unit, and</p> <p style="padding-left: 20px;">causing a switch associated with said intermediate input means to connect the output of a player associated with said recorder to at least one selected processor at a selected time,</p> <p style="padding-left: 20px;">thereby to enable said intermediate input means to input data of said selected data unit to said selected</p>

<p><u>transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u> transferring said at least one instruct signal to at least one transmitter; <u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and</u> transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	<p>processor and cause said processor to process said input data.</p>
---	---

Application Claim 142	U.S. Pat. No. 5,109,414, Claim 24
<p>142. A method of outputting a video presentation at a receiver station, <u>said video presentation including a video image</u>, said method comprising the steps of: receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal; detecting said at least a first discrete signal and said at least one control signal in said information transmission; passing said detected at least a first discrete signal to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p>	<p>24. A method of inputting data in a system that consists of a first input means, at least one intermediate input means, and a plurality of processors consisting of the steps of: transmitting a plurality of data units, causing recorder means associated with a selected intermediate input means to record a selected data unit, and causing a switch associated with said intermediate input means to connect the output of a player associated with said recorder to at least one selected processor at a selected time, thereby to enable said intermediate input means to input data of said selected data unit to said selected processor and cause said processor to process said input data.</p>

<p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	
---	--

Application Claim 143	U.S. Pat. No. 5,109,414, Claim 24
<p>143. A method of outputting a video presentation at a receiver station including:</p> <p><u>receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal;</u></p> <p><u>passing said received video image to an output device for delivery to a user;</u></p> <p>detecting said at least one first discrete signal;</p> <p>passing information contained in said at least one first discrete signal to a processor in response to said step of detecting;</p> <p><u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u></p> <p>responding, at said processor, to <u>processor instructions comprising said organized information,</u> based on said step of organizing;</p> <p>generating a signal based on said processor instructions; and</p> <p><u>outputting at least a portion of said video presentation based on said generated signal.</u></p>	<p>24. A method of inputting data in a system that consists of a first input means, at least one intermediate input means, and a plurality of processors consisting of the steps of:</p> <p>transmitting a plurality of data units,</p> <p>causing recorder means associated with a selected intermediate input means to record a selected data unit, and</p> <p>causing a switch associated with said intermediate input means to connect the output of a player associated with said recorder to at least one selected processor at a selected time,</p> <p>thereby to enable said intermediate input means to input data of said selected data unit to said selected processor and cause said processor to process said input data.</p>

Application Claim 152	U.S. Pat. No. 5,109,414, Claim 24
<p>152. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process <u>downloadable processor instructions that, at said at least one receiver</u></p>	<p>24. A method of inputting data in a system that consists of a first input means, at least one intermediate input means, and a plurality of processors consisting of the steps of:</p> <p>transmitting a plurality of data units,</p> <p>causing recorder means associated with a selected intermediate input means to record a selected data</p>

<p><u>station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</u></p> <p>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and <u>wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>unit, and</p> <p>causing a switch associated with said intermediate input means to connect the output of a player associated with said recorder to at least one selected processor at a selected time,</p> <p>thereby to enable said intermediate input means to input data of said selected data unit to said selected processor and cause said processor to process said input data.</p>
---	---

Application Claim 157	U.S. Pat. No. 5,109,414, Claim 24
<p>157. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p><u>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</u></p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p>	<p>24. A method of inputting data in a system that consists of a first input means, at least one intermediate input means, and a plurality of processors consisting of the steps of:</p> <p>transmitting a plurality of data units,</p> <p>causing recorder means associated with a selected intermediate input means to record a selected data unit, and</p> <p>causing a switch associated with said intermediate input means to connect the output of a player associated with said recorder to at least one selected processor at a selected time,</p> <p>thereby to enable said intermediate input means to input data of said selected data unit to said selected processor and cause said processor to process said input data.</p>

<p>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</p> <p>transmitting said one or more control signals from said origination transmitter before a specific time.</p>	
---	--

Application Claim 162	U.S. Pat. No. 5,109,414, Claim 24
<p>162. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals</u>, said method comprising the steps of:</p> <p><u>receiving a video image at a transmitter station;</u> <u>delivering said video image to a transmitter;</u> <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> transferring said at least said first of said plurality of discrete signals to said transmitter; and <u>transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</u></p>	<p>24. A method of inputting data in a system that consists of a first input means, at least one intermediate input means, and a plurality of processors consisting of the steps of:</p> <p>transmitting a plurality of data units, causing recorder means associated with a selected intermediate input means to record a selected data unit, and causing a switch associated with said intermediate input means to connect the output of a player associated with said recorder to at least one selected processor at a selected time, thereby to enable said intermediate input means to input data of said selected data unit to said selected processor and cause said processor to process said input data.</p>

Application Claim 167	U.S. Pat. No. 5,109,414, Claim 24
<p>167. A method of outputting a video graphic presentation at a receiver station including:</p> <p><u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-</u></p>	<p>24. A method of inputting data in a system that consists of a first input means, at least one intermediate input means, and a plurality of processors consisting of the steps of:</p> <p>transmitting a plurality of data units, causing recorder means associated with a selected</p>

<p><u>screen video graphic image containing at least one graphic image;</u> <u>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> detecting said at least a first discrete signal of said downloadable code; passing said at least a first discrete signal of said downloadable code to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> passing, to said video monitor based on said step of responding to at least one processor instruction, <u>only a portion of a second completed full-screen video graphic image;</u> and <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>intermediate input means to record a selected data unit, and causing a switch associated with said intermediate input means to connect the output of a player associated with said recorder to at least one selected processor at a selected time, thereby to enable said intermediate input means to input data of said selected data unit to said selected processor and cause said processor to process said input data.</p>
--	--

Application Claim 171	U.S. Pat. No. 5,109,414, Claim 24
<p>171. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, <u>wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein</u></p>	<p>24. A method of inputting data in a system that consists of a first input means, at least one intermediate input means, and a plurality of processors consisting of the steps of: transmitting a plurality of data units, causing recorder means associated with a selected intermediate input means to record a selected data unit, and causing a switch associated with said intermediate input means to connect the output of a player associated with said recorder to at least one selected processor at a selected time,</p>

said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;

transferring said at least one discrete signal to a transmitter;

receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said at least one discrete signal and said one or more control signals,

wherein said method delivers said video graphic presentation.

thereby to enable said intermediate input means to input data of said selected data unit to said selected processor and cause said processor to process said input data.

Application Claim 175	U.S. Pat. No. 5,109,414, Claim 24
<p>175. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said</p>	<p>24. A method of inputting data in a system that consists of a first input means, at least one intermediate input means, and a plurality of processors consisting of the steps of: transmitting a plurality of data units, causing recorder means associated with a selected intermediate input means to record a selected data</p>

<p>method comprising the steps of:</p> <p><u>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</u></p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</p> <p><u>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>unit, and</p> <p>causing a switch associated with said intermediate input means to connect the output of a player associated with said recorder to at least one selected processor at a selected time,</p> <p>thereby to enable said intermediate input means to input data of said selected data unit to said selected processor and cause said processor to process said input data.</p>
--	---

Application Claim 177	U.S. Pat. No. 5,109,414, Claim 24
<p>177. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</p>	<p>24. A method of inputting data in a system that consists of a first input means, at least one intermediate input means, and a plurality of processors consisting of the steps of:</p> <p>transmitting a plurality of data units,</p> <p>causing recorder means associated with a selected intermediate input means to record a selected data unit, and</p>

<p><u>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</u> <u>delivering said received first completed full-screen video graphic image to a transmitter;</u> <u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u> <u>transferring said one or more instruct signals to said transmitter; and</u> <u>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>causing a switch associated with said intermediate input means to connect the output of a player associated with said recorder to at least one selected processor at a selected time, thereby to enable said intermediate input means to input data of said selected data unit to said selected processor and cause said processor to process said input data.</p>
---	--

Application Claim 179	U.S. Pat. No. 5,109,414, Claim 24
<p>179. A method of outputting a video graphic presentation at a receiver station including: receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image; <u>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> detecting said at least a first discrete signal;</p>	<p>24. A method of inputting data in a system that consists of a first input means, at least one intermediate input means, and a plurality of processors consisting of the steps of: transmitting a plurality of data units, causing recorder means associated with a selected intermediate input means to record a selected data unit, and causing a switch associated with said intermediate input means to connect the output of a player associated with said recorder to at least one selected processor at a selected time, thereby to enable said intermediate input means to input data of said selected data unit to said selected processor and cause said processor to process said</p>

<p>passing said at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u></p> <p><u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>input data.</p>
--	--------------------

Application Claim 56	U.S. Pat. No. 5,109,414, Claim 25
<p>56. A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying <u>a video presentation comprising a locally generated image and an image received from a remote video source</u>, said method comprising the steps of:</p> <p style="padding-left: 2em;"><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p style="padding-left: 2em;"><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p style="padding-left: 2em;"><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p style="padding-left: 2em;"><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p style="padding-left: 2em;">and</p> <p style="padding-left: 2em;"><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>25. A method of communicating television programming in a system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one matrix switch, one video recorder and one video player with at least one of said detectors pre-programmed to detect program identification information, consisting of the steps of:</p> <p style="padding-left: 2em;">transmitting programming in a selected television transmission,</p> <p style="padding-left: 2em;">transmitting a control signal to said control processor that causes said control processor to control said matrix switch, detecting said control signal at a selected detector, combining for transmission to said information of said control signal and said detector identification information and</p> <p style="padding-left: 2em;">causing said control processor to transmit control information to said switch</p> <p style="padding-left: 2em;">thereby to cause said switch to direct the programming of said selected transmission to at least one selected processor.</p>

Application Claim 75	U.S. Pat. No. 5,109,414, Claim 25
<p>75. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, <u>said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image</u>, said method comprising the steps of:</p> <p style="padding-left: 2em;"><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image</u>, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</p> <p style="padding-left: 2em;">transferring said downloadable processor</p>	<p>25. A method of communicating television programming in a system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one matrix switch, one video recorder and one video player with at least one of said detectors pre-programmed to detect program identification information, consisting of the steps of:</p> <p style="padding-left: 2em;">transmitting programming in a selected television transmission,</p> <p style="padding-left: 2em;">transmitting a control signal to said control processor that causes said control processor to control said matrix switch, detecting said control signal at a selected detector, combining for transmission to said information of said control signal and said detector identification information and</p> <p style="padding-left: 2em;">causing said control processor to transmit control information to said switch</p> <p style="padding-left: 2em;">thereby to cause said switch to direct the programming of said selected transmission to at least one selected processor.</p>

<p>instructions to a transmitter;</p> <p>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</p> <p>transferring said at least one control signal to said transmitter; and</p> <p>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	
---	--

Application Claim 80	U.S. Pat. No. 5,109,414, Claim 25
<p>80. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u></p> <p>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</p> <p>transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>25. A method of communicating television programming in a system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one matrix switch, one video recorder and one video player with at least one of said detectors pre-programmed to detect program identification information, consisting of the steps of:</p> <p>transmitting programming in a selected television transmission,</p> <p>transmitting a control signal to said control processor that causes said control processor to control said matrix switch, detecting said control signal at a selected detector, combining for transmission to said information of said control signal and said detector identification information and</p> <p>causing said control processor to transmit control information to said switch</p> <p>thereby to cause said switch to direct the programming of said selected transmission to at least one selected processor.</p>

Application Claim 84	U.S. Pat. No. 5,109,414, Claim 25
<p>84. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is</p>	<p>25. A method of communicating television programming in a system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one</p>

<p>adapted to detect the presence of at least one signal, <u>wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals</u> and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving video at a transmitter station; delivering said video to a transmitter; <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and transmitting said video and said first discrete signal to said at least one receiver station. 	<p>detector, one matrix switch, one video recorder and one video player with at least one of said detectors pre-programmed to detect program identification information, consisting of the steps of:</p> <ul style="list-style-type: none"> transmitting programming in a selected television transmission, transmitting a control signal to said control processor that causes said control processor to control said matrix switch, detecting said control signal at a selected detector, combining for transmission to said information of said control signal and said detector identification information and causing said control processor to transmit control information to said switch thereby to cause said switch to direct the programming of said selected transmission to at least one selected processor.
---	---

Application Claim 93	U.S. Pat. No. 5,109,414, Claim 25
<p>93. A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal; detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission; passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor; <u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing; responding to said at least one processor instruction 	<p>25. A method of communicating television programming in a system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one matrix switch, one video recorder and one video player with at least one of said detectors pre-programmed to detect program identification information, consisting of the steps of:</p> <ul style="list-style-type: none"> transmitting programming in a selected television transmission, transmitting a control signal to said control processor that causes said control processor to control said matrix switch, detecting said control signal at a selected detector, combining for transmission to said information of said control signal and said detector identification information and causing said control processor to transmit control information to said switch thereby to cause said switch to direct the programming of said selected transmission to at least one selected processor.

<p>at said receiver station based on said step of passing said at least one processor instruction; <u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	
---	--

Application Claim 110	U.S. Pat. No. 5,109,414, Claim 25
<p>110. A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</p> <p><u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u></p> <p>transferring said at least said first discrete signal to at least one transmitter;</p> <p><u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u></p> <p>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>25. A method of communicating television programming in a system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one matrix switch, one video recorder and one video player with at least one of said detectors pre-programmed to detect program identification information, consisting of the steps of:</p> <p>transmitting programming in a selected television transmission,</p> <p>transmitting a control signal to said control processor that causes said control processor to control said matrix switch, detecting said control signal at a selected detector, combining for transmission to said information of said control signal and said detector identification information and</p> <p>causing said control processor to transmit control information to said switch</p> <p>thereby to cause said switch to direct the programming of said selected transmission to at least one selected processor.</p>

Application Claim 116	U.S. Pat. No. 5,109,414, Claim 25
-----------------------	-----------------------------------

<p>116. A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, <u>wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction</u>, said method comprising the steps of:</p> <p style="padding-left: 20px;"><u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u></p> <p style="padding-left: 20px;">receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</p> <p style="padding-left: 20px;">transferring said at least one control signal to said at least one origination transmitter before a specific time; and</p> <p style="padding-left: 20px;">transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	<p>25. A method of communicating television programming in a system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one matrix switch, one video recorder and one video player with at least one of said detectors pre-programmed to detect program identification information, consisting of the steps of:</p> <p style="padding-left: 20px;">transmitting programming in a selected television transmission,</p> <p style="padding-left: 20px;">transmitting a control signal to said control processor that causes said control processor to control said matrix switch, detecting said control signal at a selected detector, combining for transmission to said information of said control signal and said detector identification information and</p> <p style="padding-left: 20px;">causing said control processor to transmit control information to said switch</p> <p style="padding-left: 20px;">thereby to cause said switch to direct the programming of said selected transmission to at least one selected processor.</p>
--	---

Application Claim 123	U.S. Pat. No. 5,109,414, Claim 25
<p>123. A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</p> <p style="padding-left: 20px;"><u>receiving at at least one of said first remote</u></p>	<p>25. A method of communicating television programming in a system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one matrix switch, one video recorder and one video player with at least one of said detectors pre-programmed to detect program identification information, consisting of the steps of:</p> <p style="padding-left: 20px;">transmitting programming in a selected television transmission,</p> <p style="padding-left: 20px;">transmitting a control signal to said control processor that causes said control processor to control said matrix switch, detecting said control signal at a selected detector, combining for transmission to said</p>

<p><u>transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u> transferring said at least one instruct signal to at least one transmitter; receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	<p>information of said control signal and said detector identification information and causing said control processor to transmit control information to said switch thereby to cause said switch to direct the programming of said selected transmission to at least one selected processor.</p>
--	---

Application Claim 142	U.S. Pat. No. 5,109,414, Claim 25
<p>142. A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of: receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal; detecting said at least a first discrete signal and said at least one control signal in said information transmission; passing said detected at least a first discrete signal to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p>	<p>25. A method of communicating television programming in a system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one matrix switch, one video recorder and one video player with at least one of said detectors pre-programmed to detect program identification information, consisting of the steps of: transmitting programming in a selected television transmission, transmitting a control signal to said control processor that causes said control processor to control said matrix switch, detecting said control signal at a selected detector, combining for transmission to said information of said control signal and said detector identification information and</p>

<p>passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing; responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; <u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>causing said control processor to transmit control information to said switch thereby to cause said switch to direct the programming of said selected transmission to at least one selected processor.</p>
--	--

Application Claim 143	U.S. Pat. No. 5,109,414, Claim 25
<p>143. A method of outputting a video presentation at a receiver station including: receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to processor instructions comprising said organized information, based on said step of organizing; generating a signal based on said processor instructions; and <u>outputting at least a portion of said video presentation based on said generated signal.</u></p>	<p>25. A method of communicating television programming in a system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one matrix switch, one video recorder and one video player with at least one of said detectors pre-programmed to detect program identification information, consisting of the steps of: transmitting programming in a selected television transmission, transmitting a control signal to said control processor that causes said control processor to control said matrix switch, detecting said control signal at a selected detector, combining for transmission to said information of said control signal and said detector identification information and causing said control processor to transmit control information to said switch thereby to cause said switch to direct the programming of said selected transmission to at least one selected processor.</p>

Application Claim 152	U.S. Pat. No. 5,109,414, Claim 25
<p>152. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process <u>downloadable processor instructions that, at said at least one receiver</u></p>	<p>25. A method of communicating television programming in a system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one matrix switch, one video recorder and one video player with at least one of said detectors pre-programmed to detect program identification</p>

<p><u>station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</u></p> <p>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p><u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>information, consisting of the steps of:</p> <p>transmitting programming in a selected television transmission,</p> <p>transmitting a control signal to said control processor that causes said control processor to control said matrix switch, detecting said control signal at a selected detector, combining for transmission to said information of said control signal and said detector identification information and</p> <p>causing said control processor to transmit control information to said switch</p> <p>thereby to cause said switch to direct the programming of said selected transmission to at least one selected processor.</p>
---	---

Application Claim 157	U.S. Pat. No. 5,109,414, Claim 25
<p>157. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p>	<p>25. A method of communicating television programming in a system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one matrix switch, one video recorder and one video player with at least one of said detectors pre-programmed to detect program identification information, consisting of the steps of:</p> <p>transmitting programming in a selected television transmission,</p> <p>transmitting a control signal to said control processor that causes said control processor to control said matrix switch, detecting said control signal at a selected detector, combining for transmission to said information of said control signal and said detector identification information and</p>

<p>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</p> <p>transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>causing said control processor to transmit control information to said switch</p> <p>thereby to cause said switch to direct the programming of said selected transmission to at least one selected processor.</p>
---	--

Application Claim 162	U.S. Pat. No. 5,109,414, Claim 25
<p>162. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals</u>, said method comprising the steps of:</p> <p>receiving a video image at a transmitter station;</p> <p>delivering said video image to a transmitter;</p> <p><u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u></p> <p>transferring said at least said first of said plurality of discrete signals to said transmitter; and</p> <p>transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>25. A method of communicating television programming in a system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one matrix switch, one video recorder and one video player with at least one of said detectors pre-programmed to detect program identification information, consisting of the steps of:</p> <p>transmitting programming in a selected television transmission,</p> <p>transmitting a control signal to said control processor that causes said control processor to control said matrix switch, detecting said control signal at a selected detector, combining for transmission to said information of said control signal and said detector identification information and</p> <p>causing said control processor to transmit control information to said switch</p> <p>thereby to cause said switch to direct the programming of said selected transmission to at least one selected processor.</p>

Application Claim 167	U.S. Pat. No. 5,109,414, Claim 25
<p>167. A method of outputting a video graphic presentation at a receiver station including:</p> <p><u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-</u></p>	<p>25. A method of communicating television programming in a system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one matrix switch, one video recorder and one video player with at least one of said detectors</p>

<p><u>screen video graphic image containing at least one graphic image;</u> passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen; displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen; detecting said at least a first discrete signal of said downloadable code; passing said at least a first discrete signal of said downloadable code to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing; passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image, wherein said method delivers said video graphic presentation.</p>	<p>pre-programmed to detect program identification information, consisting of the steps of: transmitting programming in a selected television transmission, transmitting a control signal to said control processor that causes said control processor to control said matrix switch, detecting said control signal at a selected detector, combining for transmission to said information of said control signal and said detector identification information and causing said control processor to transmit control information to said switch thereby to cause said switch to direct the programming of said selected transmission to at least one selected processor.</p>
--	---

Application Claim 171	U.S. Pat. No. 5,109,414, Claim 25
<p>171. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, <u>wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein</u></p>	<p>25. A method of communicating television programming in a system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one matrix switch, one video recorder and one video player with at least one of said detectors pre-programmed to detect program identification information, consisting of the steps of: transmitting programming in a selected television transmission, transmitting a control signal to said control processor that causes said control processor to control</p>

<p><u>said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:</u></p> <p><u>receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</u></p> <p>transferring said at least one discrete signal to a transmitter;</p> <p><u>receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said at least one discrete signal and said one or more control signals,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>said matrix switch, detecting said control signal at a selected detector, combining for transmission to said information of said control signal and said detector identification information and</p> <p>causing said control processor to transmit control information to said switch</p> <p>thereby to cause said switch to direct the programming of said selected transmission to at least one selected processor.</p>
--	--

Application Claim 175	U.S. Pat. No. 5,109,414, Claim 25
<p>175. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said</p>	<p>25. A method of communicating television programming in a system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one matrix switch, one video recorder and one video player with at least one of said detectors pre-programmed to detect program identification</p>

<p>method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</p> <p>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>information, consisting of the steps of:</p> <p>transmitting programming in a selected television transmission,</p> <p>transmitting a control signal to said control processor that causes said control processor to control said matrix switch, detecting said control signal at a selected detector, combining for transmission to said information of said control signal and said detector identification information and</p> <p>causing said control processor to transmit control information to said switch</p> <p>thereby to cause said switch to direct the programming of said selected transmission to at least one selected processor.</p>
---	---

Application Claim 177	U.S. Pat. No. 5,109,414, Claim 25
<p>177. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</p>	<p>25. A method of communicating television programming in a system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one matrix switch, one video recorder and one video player with at least one of said detectors pre-programmed to detect program identification information, consisting of the steps of:</p>

<p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>transferring said one or more instruct signals to said transmitter; and</p> <p>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>transmitting programming in a selected television transmission,</p> <p>transmitting a control signal to said control processor that causes said control processor to control said matrix switch, detecting said control signal at a selected detector, combining for transmission to said information of said control signal and said detector identification information and</p> <p>causing said control processor to transmit control information to said switch</p> <p>thereby to cause said switch to direct the programming of said selected transmission to at least one selected processor.</p>
--	---

Application Claim 179	U.S. Pat. No. 5,109,414, Claim 25
<p>179. A method of outputting a video graphic presentation at a receiver station including:</p> <p>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</p> <p>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal;</p>	<p>25. A method of communicating television programming in a system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one matrix switch, one video recorder and one video player with at least one of said detectors pre-programmed to detect program identification information, consisting of the steps of:</p> <p>transmitting programming in a selected television transmission,</p> <p>transmitting a control signal to said control processor that causes said control processor to control said matrix switch, detecting said control signal at a selected detector, combining for transmission to said information of said control signal and said detector</p>

passing said at least a first discrete signal to at least one processor;

organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;

responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;

passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and

displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,

wherein said method delivers said video graphic presentation.

identification information and

causing said control processor to transmit control information to said switch

thereby to cause said switch to direct the programming of said selected transmission to at least one selected processor.

Application Claim 56	U.S. Pat. No. 5,109,414, Claim 26
<p>56. A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying <u>a video presentation comprising a locally generated image and an image received from a remote video source</u>, said method comprising the steps of:</p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p>and</p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>26. A method of communicating television programming in a system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one video recorder and one video player with at least one said detectors pre-programmed to detect program identification information, consisting of the steps of:</p> <p>transmitting a plurality of units of television pre-programming containing embedded program identification information,</p> <p>causing a selected receiving station to record a selected television program unit,</p> <p>causing said station to position the start of said program unit at the play head of a video player,</p> <p>causing said player thereafter to play and transmit at a selected time</p> <p>thereby to cause said selected station to transmit said selected unit at said selected time.</p>

Application Claim 75	U.S. Pat. No. 5,109,414, Claim 26
<p>75. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, <u>said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image</u>, said method comprising the steps of:</p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image</u>, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</p> <p>transferring said downloadable processor</p>	<p>26. A method of communicating television programming in a system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one video recorder and one video player with at least one said detectors pre-programmed to detect program identification information, consisting of the steps of:</p> <p>transmitting a plurality of units of television pre-programming containing embedded program identification information,</p> <p>causing a selected receiving station to record a selected television program unit,</p> <p>causing said station to position the start of said program unit at the play head of a video player,</p> <p>causing said player thereafter to play and transmit at a selected time</p> <p>thereby to cause said selected station to transmit said selected unit at said selected time.</p>

<p>instructions to a transmitter; receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation; transferring said at least one control signal to said transmitter; and transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	
---	--

Application Claim 80	U.S. Pat. No. 5,109,414, Claim 26
<p>80. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of: receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station; <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>26. A method of communicating television programming in a system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one video recorder and one video player with at least one said detectors pre-programmed to detect program identification information, consisting of the steps of: transmitting a plurality of units of television pre-programming containing embedded program identification information, causing a selected receiving station to record a selected television program unit, causing said station to position the start of said program unit at the play head of a video player, causing said player thereafter to play and transmit at a selected time thereby to cause said selected station to transmit said selected unit at said selected time.</p>

Application Claim 84	U.S. Pat. No. 5,109,414, Claim 26
<p>84. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is</p>	<p>26. A method of communicating television programming in a system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one</p>

<p>adapted to detect the presence of at least one signal, <u>wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals</u> and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving video at a transmitter station; delivering said video to a transmitter; <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and transmitting said video and said first discrete signal to said at least one receiver station. 	<p>detector, one video recorder and one video player with at least one said detectors pre-programmed to detect program identification information, consisting of the steps of:</p> <ul style="list-style-type: none"> transmitting a plurality of units of television pre-programming containing embedded program identification information, causing a selected receiving station to record a selected television program unit, causing said station to position the start of said program unit at the play head of a video player, causing said player thereafter to play and transmit at a selected time thereby to cause said selected station to transmit said selected unit at said selected time.
---	---

Application Claim 93	U.S. Pat. No. 5,109,414, Claim 26
<p>93. A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal; detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission; passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor; <u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing; responding to said at least one processor instruction 	<p>26. A method of communicating television programming in a system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one video recorder and one video player with at least one said detectors pre-programmed to detect program identification information, consisting of the steps of:</p> <ul style="list-style-type: none"> transmitting a plurality of units of television pre-programming containing embedded program identification information, causing a selected receiving station to record a selected television program unit, causing said station to position the start of said program unit at the play head of a video player, causing said player thereafter to play and transmit at a selected time thereby to cause said selected station to transmit said selected unit at said selected time.

<p>at said receiver station based on said step of passing said at least one processor instruction; <u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	
---	--

Application Claim 110	U.S. Pat. No. 5,109,414, Claim 26
<p>110. A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</p> <p><u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u></p> <p>transferring said at least said first discrete signal to at least one transmitter;</p> <p><u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u></p> <p>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>26. A method of communicating television programming in a system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one video recorder and one video player with at least one said detectors pre-programmed to detect program identification information, consisting of the steps of:</p> <p>transmitting a plurality of units of television pre-programming containing embedded program identification information,</p> <p>causing a selected receiving station to record a selected television program unit,</p> <p>causing said station to position the start of said program unit at the play head of a video player,</p> <p>causing said player thereafter to play and transmit at a selected time</p> <p>thereby to cause said selected station to transmit said selected unit at said selected time.</p>

Application Claim 116	U.S. Pat. No. 5,109,414, Claim 26
-----------------------	-----------------------------------

<p>116. A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, <u>wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction</u>, said method comprising the steps of:</p> <p style="padding-left: 40px;"><u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u></p> <p style="padding-left: 40px;">receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</p> <p style="padding-left: 40px;">transferring said at least one control signal to said at least one origination transmitter before a specific time; and</p> <p style="padding-left: 40px;">transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	<p>26. A method of communicating television programming in a system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one video recorder and one video player with at least one said detectors pre-programmed to detect program identification information, consisting of the steps of:</p> <p style="padding-left: 40px;">transmitting a plurality of units of television pre-programming containing embedded program identification information,</p> <p style="padding-left: 40px;">causing a selected receiving station to record a selected television program unit,</p> <p style="padding-left: 40px;">causing said station to position the start of said program unit at the play head of a video player,</p> <p style="padding-left: 40px;">causing said player thereafter to play and transmit at a selected time</p> <p style="padding-left: 40px;">thereby to cause said selected station to transmit said selected unit at said selected time.</p>
--	---

Application Claim 123	U.S. Pat. No. 5,109,414, Claim 26
<p>123. A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</p> <p style="padding-left: 40px;"><u>receiving at at least one of said first remote</u></p>	<p>26. A method of communicating television programming in a system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one video recorder and one video player with at least one said detectors pre-programmed to detect program identification information, consisting of the steps of:</p> <p style="padding-left: 40px;">transmitting a plurality of units of television pre-programming containing embedded program identification information,</p> <p style="padding-left: 40px;">causing a selected receiving station to record a selected television program unit,</p> <p style="padding-left: 40px;">causing said station to position the start of said</p>

<p><u>transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p>transferring said at least one instruct signal to at least one transmitter;</p> <p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and</u></p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	<p>program unit at the play head of a video player, causing said player thereafter to play and transmit at a selected time</p> <p>thereby to cause said selected station to transmit said selected unit at said selected time.</p>
---	--

Application Claim 142	U.S. Pat. No. 5,109,414, Claim 26
<p>142. A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p>	<p>26. A method of communicating television programming in a system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one video recorder and one video player with at least one said detectors pre-programmed to detect program identification information, consisting of the steps of:</p> <p>transmitting a plurality of units of television pre-programming containing embedded program identification information,</p> <p>causing a selected receiving station to record a selected television program unit,</p> <p>causing said station to position the start of said program unit at the play head of a video player, causing said player thereafter to play and transmit</p>

<p>passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing; responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; <u>generating only a portion of said video image based on said step of responding to said at least one processor instruction;</u> and <u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>at a selected time thereby to cause said selected station to transmit said selected unit at said selected time.</p>
--	---

Application Claim 143	U.S. Pat. No. 5,109,414, Claim 26
<p>143. A method of outputting a video presentation at a receiver station including: receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to processor instructions comprising said organized information, based on said step of organizing; generating a signal based on said processor instructions; and <u>outputting at least a portion of said video presentation based on said generated signal.</u></p>	<p>26. A method of communicating television programming in a system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one video recorder and one video player with at least one said detectors pre-programmed to detect program identification information, consisting of the steps of: transmitting a plurality of units of television pre-programming containing embedded program identification information, causing a selected receiving station to record a selected television program unit, causing said station to position the start of said program unit at the play head of a video player, causing said player thereafter to play and transmit at a selected time thereby to cause said selected station to transmit said selected unit at said selected time.</p>

Application Claim 152	U.S. Pat. No. 5,109,414, Claim 26
<p>152. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process <u>downloadable processor instructions that, at said at least one receiver</u></p>	<p>26. A method of communicating television programming in a system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one video recorder and one video player with at least one said detectors pre-programmed to detect program identification information, consisting</p>

<p><u>station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</u></p> <p>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p><u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>of the steps of:</p> <p>transmitting a plurality of units of television pre-programming containing embedded program identification information,</p> <p>causing a selected receiving station to record a selected television program unit,</p> <p>causing said station to position the start of said program unit at the play head of a video player,</p> <p>causing said player thereafter to play and transmit at a selected time</p> <p>thereby to cause said selected station to transmit said selected unit at said selected time.</p>
---	---

Application Claim 157	U.S. Pat. No. 5,109,414, Claim 26
<p>157. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p>	<p>26. A method of communicating television programming in a system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one video recorder and one video player with at least one said detectors pre-programmed to detect program identification information, consisting of the steps of:</p> <p>transmitting a plurality of units of television pre-programming containing embedded program identification information,</p> <p>causing a selected receiving station to record a selected television program unit,</p> <p>causing said station to position the start of said program unit at the play head of a video player,</p> <p>causing said player thereafter to play and transmit</p>

<p>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</p> <p>transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>at a selected time</p> <p>thereby to cause said selected station to transmit said selected unit at said selected time.</p>
---	---

Application Claim 162	U.S. Pat. No. 5,109,414, Claim 26
<p>162. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals</u>, said method comprising the steps of:</p> <p>receiving a video image at a transmitter station;</p> <p>delivering said video image to a transmitter;</p> <p><u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u></p> <p>transferring said at least said first of said plurality of discrete signals to said transmitter; and</p> <p>transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>26. A method of communicating television programming in a system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one video recorder and one video player with at least one said detectors pre-programmed to detect program identification information, consisting of the steps of:</p> <p>transmitting a plurality of units of television pre-programming containing embedded program identification information,</p> <p>causing a selected receiving station to record a selected television program unit,</p> <p>causing said station to position the start of said program unit at the play head of a video player,</p> <p>causing said player thereafter to play and transmit at a selected time</p> <p>thereby to cause said selected station to transmit said selected unit at said selected time.</p>

Application Claim 167	U.S. Pat. No. 5,109,414, Claim 26
<p>167. A method of outputting a video graphic presentation at a receiver station including:</p> <p><u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-</u></p>	<p>26. A method of communicating television programming in a system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one video recorder and one video player with at least one said detectors pre-programmed to</p>

<p><u>screen video graphic image containing at least one graphic image;</u> passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen; displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen; detecting said at least a first discrete signal of said downloadable code; passing said at least a first discrete signal of said downloadable code to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing; <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> wherein said method delivers said video graphic presentation.</p>	<p>detect program identification information, consisting of the steps of: transmitting a plurality of units of television pre-programming containing embedded program identification information, causing a selected receiving station to record a selected television program unit, causing said station to position the start of said program unit at the play head of a video player, causing said player thereafter to play and transmit at a selected time thereby to cause said selected station to transmit said selected unit at said selected time.</p>
--	---

Application Claim 171	U.S. Pat. No. 5,109,414, Claim 26
<p>171. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, <u>wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein</u></p>	<p>26. A method of communicating television programming in a system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one video recorder and one video player with at least one said detectors pre-programmed to detect program identification information, consisting of the steps of: transmitting a plurality of units of television pre-programming containing embedded program identification information, causing a selected receiving station to record a</p>

<p><u>said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:</u></p> <p><u>receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</u></p> <p>transferring said at least one discrete signal to a transmitter;</p> <p><u>receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said at least one discrete signal and said one or more control signals,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>selected television program unit,</p> <p>causing said station to position the start of said program unit at the play head of a video player,</p> <p>causing said player thereafter to play and transmit at a selected time</p> <p>thereby to cause said selected station to transmit said selected unit at said selected time.</p>
--	---

Application Claim 175	U.S. Pat. No. 5,109,414, Claim 26
<p>175. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said</p>	<p>26. A method of communicating television programming in a system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one video recorder and one video player with at least one said detectors pre-programmed to detect program identification information, consisting</p>

<p>method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</p> <p>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>of the steps of:</p> <p>transmitting a plurality of units of television pre-programming containing embedded program identification information,</p> <p>causing a selected receiving station to record a selected television program unit,</p> <p>causing said station to position the start of said program unit at the play head of a video player,</p> <p>causing said player thereafter to play and transmit at a selected time</p> <p>thereby to cause said selected station to transmit said selected unit at said selected time.</p>
---	---

Application Claim 177	U.S. Pat. No. 5,109,414, Claim 26
<p>177. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</p>	<p>26. A method of communicating television programming in a system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one video recorder and one video player with at least one said detectors pre-programmed to detect program identification information, consisting of the steps of:</p>

<p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>transferring said one or more instruct signals to said transmitter; and</p> <p>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>transmitting a plurality of units of television pre-programming containing embedded program identification information,</p> <p>causing a selected receiving station to record a selected television program unit,</p> <p>causing said station to position the start of said program unit at the play head of a video player,</p> <p>causing said player thereafter to play and transmit at a selected time</p> <p>thereby to cause said selected station to transmit said selected unit at said selected time.</p>
--	---

Application Claim 179	U.S. Pat. No. 5,109,414, Claim 26
<p>179. A method of outputting a video graphic presentation at a receiver station including:</p> <p>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</p> <p>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal;</p>	<p>26. A method of communicating television programming in a system that consists of a transmission station and a plurality of receiving stations, each receiving station having at least one detector, one video recorder and one video player with at least one said detectors pre-programmed to detect program identification information, consisting of the steps of:</p> <p>transmitting a plurality of units of television pre-programming containing embedded program identification information,</p> <p>causing a selected receiving station to record a selected television program unit,</p> <p>causing said station to position the start of said program unit at the play head of a video player,</p>

<p>passing said at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u></p> <p><u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u></p> <p>wherein said method delivers said video graphic presentation.</p>	<p>causing said player thereafter to play and transmit at a selected time</p> <p>thereby to cause said selected station to transmit said selected unit at said selected time.</p>
--	---

Application Claim 56	U.S. Pat. No. 5,233,654, Claim 1
<p>56. A method for receiving and processing data for use with an interactive video apparatus, <u>said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source</u>, said method comprising the steps of:</p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p>communicating one of said at least said first request and a second request to a remote data source;</p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p>and</p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>1. A system for inputting, processing and collecting response information from members of an audience consisting of a plurality of audience stations, each station accommodating a specific audience member and each station having read/write memory means capable of holding specific data of its audience member, input means for inputting information of its audience member, first storage means for holding its audience member's input, processor means for processing its audience member's input and assembling output records that hold additional information besides said input, second storage means for holding said output records, and transmission means for transferring the output of said second storage means, with at least some of said stations programmed to process input information in a predetermined fashion,</p> <p>a transmission medium for conveying the output of the transmission means of at least some of said audience stations, and</p> <p>at least one data collection station for receiving the output records of said audience stations, processing said records, and collecting the information of said records.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 5,233,654, Claim 1
<p>75. A method of <u>delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image</u>, said method comprising the steps of:</p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable</u></p>	<p>1. A system for inputting, processing and collecting response information from members of an audience consisting of a plurality of audience stations, each station accommodating a specific audience member and each station having read/write memory means capable of holding specific data of its audience member, input means for inputting information of its audience member, first storage means for holding its audience member's input, processor means for processing its audience member's input and assembling output records that hold additional information besides said input, second storage means for holding said output records, and transmission means for transferring the output of said second storage means, with at least some of said stations programmed to process input information in a predetermined fashion,</p> <p>a transmission medium for conveying the output of</p>

<p><u>processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image</u>, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</p> <p>transferring said at least one control signal to said transmitter; and</p> <p>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	<p>the transmission means of at least some of said audience stations, and</p> <p>at least one data collection station for receiving the output records of said audience stations, processing said records, and collecting the information of said records.</p>
---	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 5,233,654, Claim 1
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u></p> <p>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u></p> <p>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</p> <p>transmitting said at least one control signal from</p>	<p>1. A system for inputting, processing and collecting response information from members of an audience consisting of a plurality of audience stations, each station accommodating a specific audience member and each station having read/write memory means capable of holding specific data of its audience member, input means for inputting information of its audience member, first storage means for holding its audience member's input, processor means for processing its audience member's input and assembling output records that hold additional information besides said input, second storage means for holding said output records, and transmission means for transferring the output of said second storage means, with at least some of said stations programmed to process input information in a predetermined fashion,</p> <p>a transmission medium for conveying the output of the transmission means of at least some of said audience stations, and</p> <p>at least one data collection station for receiving the output records of said audience stations, processing said records, and collecting the information of said records.</p>

said origination transmitter before a specific time.	
--	--

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 5,233,654, Claim 1
<p>84. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</u></p> <p style="padding-left: 40px;">receiving video at a transmitter station; delivering said video to a transmitter; <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u></p> <p style="padding-left: 40px;">transferring said first discrete signal to said transmitter; and transmitting said video and said first discrete signal to said at least one receiver station.</p>	<p>1. A system for inputting, processing and collecting response information from members of an audience consisting of a plurality of audience stations, each station accommodating a specific audience member and each station having read/write memory means capable of holding specific data of its audience member, input means for inputting information of its audience member, first storage means for holding its audience member's input, processor means for processing its audience member's input and assembling output records that hold additional information besides said input, second storage means for holding said output records, and transmission means for transferring the output of said second storage means, with at least some of said stations programmed to process input information in a predetermined fashion,</p> <p style="padding-left: 40px;">a transmission medium for conveying the output of the transmission means of at least some of said audience stations, and</p> <p style="padding-left: 40px;">at least one data collection station for receiving the output records of said audience stations, processing said records, and collecting the information of said records.</p>

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 5,233,654, Claim 1
<p>93. <u>A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</u></p>	<p>1. A system for inputting, processing and collecting response information from members of an audience consisting of a plurality of audience stations, each station accommodating a specific audience member and each station having read/write memory means</p>

<p>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal;</p> <p>detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission;</p> <p>passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor;</p> <p><u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>capable of holding specific data of its audience member, input means for inputting information of its audience member, first storage means for holding its audience member's input, processor means for processing its audience member's input and assembling output records that hold additional information besides said input, second storage means for holding said output records, and transmission means for transferring the output of said second storage means, with at least some of said stations programmed to process input information in a predetermined fashion,</p> <p>a transmission medium for conveying the output of the transmission means of at least some of said audience stations, and</p> <p>at least one data collection station for receiving the output records of said audience stations, processing said records, and collecting the information of said records.</p>
--	--

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 5,233,654, Claim 1
<p>110. A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</p> <p><u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one</u></p>	<p>1. A system for inputting, processing and collecting response information from members of an audience consisting of a plurality of audience stations, each station accommodating a specific audience member and each station having read/write memory means capable of holding specific data of its audience member, input means for inputting information of its audience member, first storage means for holding its audience member's input, processor means for processing its audience member's input and assembling output records that hold additional information besides said input, second storage means for holding said output records, and transmission means for transferring the output of said second</p>

<p><u>processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u></p> <p>transferring said at least said first discrete signal to at least one transmitter;</p> <p><u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u></p> <p>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>storage means, with at least some of said stations programmed to process input information in a predetermined fashion,</p> <p>a transmission medium for conveying the output of the transmission means of at least some of said audience stations, and</p> <p>at least one data collection station for receiving the output records of said audience stations, processing said records, and collecting the information of said records.</p>
--	--

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 5,233,654, Claim 1
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u></p> <p><u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u></p> <p>receiving at least one control signal which at said remote transmitter station operates to control the</p>	<p>1. A system for inputting, processing and collecting response information from members of an audience consisting of a plurality of audience stations, each station accommodating a specific audience member and each station having read/write memory means capable of holding specific data of its audience member, input means for inputting information of its audience member, first storage means for holding its audience member's input, processor means for processing its audience member's input and assembling output records that hold additional information besides said input, second storage means for holding said output records, and transmission means for transferring the output of said second storage means, with at least some of said stations programmed to process input information in a predetermined fashion,</p> <p>a transmission medium for conveying the output of the transmission means of at least some of said audience stations, and</p> <p>at least one data collection station for receiving the output records of said audience stations, processing said records, and collecting the information of said records.</p>

communication of one of said first discrete signal and said at least one processor instruction;
transferring said at least one control signal to said at least one origination transmitter before a specific time; and
transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 5,233,654, Claim 1
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u> <u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u> transferring said at least one instruct signal to at least one transmitter; <u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an</u></p>	<p>1. A system for inputting, processing and collecting response information from members of an audience consisting of a plurality of audience stations, each station accommodating a specific audience member and each station having read/write memory means capable of holding specific data on its audience member, input means for inputting information of its audience member, first storage means for holding its audience member's input, processing means for processing its audience member's input and assembling output records that hold additional information besides said input, second storage means for holding said output records, and transmission means for transferring the output of said second storage means, with at least some of said stations programmed to process input information in a predetermined fashion, a transmission medium for conveying the output of the transmission means of at least some of said audience stations, and at least one data collection station for receiving the output records of said audience stations, processing said records, and collecting the information of said records.</p>

<p>identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and</p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	
--	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 5,233,654, Claim 1
<p>142. A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>1. A system for inputting, processing and collecting response information from members of an audience consisting of a plurality of audience stations, each station accommodating a specific audience member and each station having read/write memory means capable of holding specific data of its audience member, input means for inputting information of its audience member, first storage means for holding its audience member's input, processor means for processing its audience member's input and assembling output records that hold additional information besides said input, second storage means for holding said output records, and transmission means for transferring the output of said second storage means, with at least some of said stations programmed to process input information in a predetermined fashion,</p> <p>a transmission medium for conveying the output of the transmission means of at least some of said audience stations, and</p> <p>at least one data collection station for receiving the output records of said audience stations, processing said records, and collecting the information of said records.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 5,233,654, Claim 1
<p>143. <u>A method of outputting a video presentation</u> at a receiver station including:</p> <ul style="list-style-type: none"> receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to <u>processor instructions comprising said organized information,</u> based on said step of organizing; generating a signal based on said processor instructions; and outputting at least a portion of said video presentation based on said generated signal. 	<p>1. A system for inputting, processing and collecting response information from members of an audience consisting of a plurality of audience stations, each station accommodating a specific audience member and each station having read/write memory means capable of holding specific data of its audience member, input means for inputting information of its audience member, first storage means for holding its audience member's input, processor means for processing its audience member's input and assembling output records that hold additional information besides said input, second storage means for holding said output records, and transmission means for transferring the output of said second storage means, with at least some of said stations programmed to process input information in a predetermined fashion,</p> <ul style="list-style-type: none"> a transmission medium for conveying the output of the transmission means of at least some of said audience stations, and at least one data collection station for receiving the output records of said audience stations, processing said records, and collecting the information of said records.

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 5,233,654, Claim 1
<p>152. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process <u>downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation</u> and have a target processor to process data, <u>said video presentation comprised of said local image of said video presentation and a video image which is received at</u></p>	<p>1. A system for inputting, processing and collecting response information from members of an audience consisting of a plurality of audience stations, each station accommodating a specific audience member and each station having read/write memory means capable of holding specific data of its audience member, input means for inputting information of its audience member, first storage means for holding its audience member's input, processor means for processing its audience member's input and assembling output records that hold additional information besides said input, second storage means</p>

<p><u>said at least one receiver station from a first remote transmitter station</u>, said method comprising the steps of:</p> <p>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p><u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>for holding said output records, and transmission means for transferring the output of said second storage means, with at least some of said stations programmed to process input information in a predetermined fashion,</p> <p>a transmission medium for conveying the output of the transmission means of at least some of said audience stations, and</p> <p>at least one data collection station for receiving the output records of said audience stations, processing said records, and collecting the information of said records.</p>
---	---

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 5,233,654, Claim 1
<p>157. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p> <p>receiving, at said origination transmitter station, one</p>	<p>1. A system for inputting, processing and collecting response information from members of an audience consisting of a plurality of audience stations, each station accommodating a specific audience member and each station having read/write memory means capable of holding specific data of its audience member, input means for inputting information of its audience member, first storage means for holding its audience member's input, processor means for processing its audience member's input and assembling output records that hold additional information besides said input, second storage means for holding said output records, and transmission means for transferring the output of said second storage means, with at least some of said stations programmed to process input information in a predetermined fashion,</p>

<p>or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</p> <p>transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>a transmission medium for conveying the output of the transmission means of at least some of said audience stations, and</p> <p>at least one data collection station for receiving the output records of said audience stations, processing said records, and collecting the information of said records.</p>
---	--

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 5,233,654, Claim 1
<p>162. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals</u>, said method comprising the steps of:</p> <p>receiving a video image at a transmitter station;</p> <p>delivering said video image to a transmitter;</p> <p><u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u></p> <p>transferring said at least said first of said plurality of discrete signals to said transmitter; and</p> <p>transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>1. A system for inputting, processing and collecting response information from members of an audience consisting of a plurality of audience stations, each station accommodating a specific audience member and each station having read/write memory means capable of holding specific data of its audience member, input means for inputting information of its audience member, first storage means for holding its audience member's input, processor means for processing its audience member's input and assembling output records that hold additional information besides said input, second storage means for holding said output records, and transmission means for transferring the output of said second storage means, with at least some of said stations programmed to process input information in a predetermined fashion,</p> <p>a transmission medium for conveying the output of the transmission means of at least some of said audience stations, and</p> <p>at least one data collection station for receiving the output records of said audience stations, processing said records, and collecting the information of said records.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus.

Application Claim 167	U.S. Pat. No. 5,233,654, Claim 1
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u> receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image; passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen; displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen; detecting said at least a first discrete signal of said downloadable code; passing said at least a first discrete signal of said downloadable code to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image;</u> and <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> wherein said method delivers said video graphic presentation.</p>	<p>1. A system for inputting, processing and collecting response information from members of an audience consisting of a plurality of audience stations, each station accommodating a specific audience member and each station having read/write memory means capable of holding specific data of its audience member, input means for inputting information of its audience member, first storage means for holding its audience member's input, processor means for processing its audience member's input and assembling output records that hold additional information besides said input, second storage means for holding said output records, and transmission means for transferring the output of said second storage means, with at least some of said stations programmed to process input information in a predetermined fashion, a transmission medium for conveying the output of the transmission means of at least some of said audience stations, and at least one data collection station for receiving the output records of said audience stations, processing said records, and collecting the information of said records.</p>

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 5,233,654, Claim 1
171. <u>A method of delivering a video graphic</u>	1. A system for inputting, processing and collecting

presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;

transferring said at least one discrete signal to a transmitter;

receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said at least one discrete signal and said one or more control signals,

wherein said method delivers said video graphic presentation.

response information from members of an audience consisting of a plurality of audience stations, each station accommodating a specific audience member and each station having read/write memory means capable of holding specific data of its audience member, input means for inputting information of its audience member, first storage means for holding its audience member's input, processor means for processing its audience member's input and assembling output records that hold additional information besides said input, second storage means for holding said output records, and transmission means for transferring the output of said second storage means, with at least some of said stations programmed to process input information in a predetermined fashion,

a transmission medium for conveying the output of the transmission means of at least some of said audience stations, and

at least one data collection station for receiving the output records of said audience stations, processing said records, and collecting the information of said records.

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 5,233,654, Claim 1
<p>175. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</p> <p>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more</p>	<p>1. A system for inputting, processing and collecting response information from members of an audience consisting of a plurality of audience stations, each station accommodating a specific audience member and each station having read/write memory means capable of holding specific data of its audience member, input means for inputting information of its audience member, first storage means for holding its audience member's input, processor means for processing its audience member's input and assembling output records that hold additional information besides said input, second storage means for holding said output records, and transmission means for transferring the output of said second storage means, with at least some of said stations programmed to process input information in a predetermined fashion,</p> <p>a transmission medium for conveying the output of the transmission means of at least some of said audience stations, and</p> <p>at least one data collection station for receiving the output records of said audience stations, processing said records, and collecting the information of said records.</p>

control signals from said origination transmitter before a specific time, wherein said method delivers said video graphic presentation.	
--	--

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 5,233,654, Claim 1
<p>177. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>transferring said one or more instruct signals to said transmitter; and</p> <p>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</p> <p>wherein said method delivers said video graphic</p>	<p>1. A system for inputting, processing and collecting response information from members of an audience consisting of a plurality of audience stations, each station accommodating a specific audience member and each station having read/write memory means capable of holding specific data of its audience member, input means for inputting information of its audience member, first storage means for holding its audience member's input, processor means for processing its audience member's input and assembling output records that hold additional information besides said input, second storage means for holding said output records, and transmission means for transferring the output of said second storage means, with at least some of said stations programmed to process input information in a predetermined fashion,</p> <p>a transmission medium for conveying the output of the transmission means of at least some of said audience stations, and</p> <p>at least one data collection station for receiving the output records of said audience stations, processing said records, and collecting the information of said records.</p>

presentation.	
---------------	--

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 5,233,654, Claim 1
<p>179. <u>A method of outputting a video graphic presentation</u> at a receiver station including:</p> <p>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</p> <p>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal;</p> <p>passing said at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u></p> <p><u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u></p> <p>wherein said method delivers said video graphic presentation.</p>	<p>1. A system for inputting, processing and collecting response information from members of an audience consisting of a plurality of audience stations, each station accommodating a specific audience member and each station having read/write memory means capable of holding specific data of its audience member, input means for inputting information of its audience member, first storage means for holding its audience member's input, processor means for processing its audience member's input and assembling output records that hold additional information besides said input, second storage means for holding said output records, and transmission means for transferring the output of said second storage means, with at least some of said stations programmed to process input information in a predetermined fashion,</p> <p>a transmission medium for conveying the output of the transmission means of at least some of said audience stations, and</p> <p>at least one data collection station for receiving the output records of said audience stations, processing said records, and collecting the information of said records.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus.

Application Claim 56	U.S. Pat. No. 5,233,654, Claim 6
<p>56. A method for receiving and processing data for use with an interactive video apparatus, <u>said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source</u>, said method comprising the steps of:</p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p>communicating one of said at least said first request and a second request to a remote data source;</p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p>and</p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>6. A method for collecting audience information in a system that consists of a plurality of audience member stations and at least one data collection station, each audience member station accommodating a specific audience member and having read/write memory means capable of holding specific data of its audience member, input means for inputting information of its audience member, first storage means for holding its audience member's input, processor means for processing its audience member's input and assembling output records that hold additional information besides said input, second storage means for holding said output records, and transmission means for transferring the output of said second storage means, with at least some of said stations programmed to process input information in a predetermined fashion and to transfer associated record information to a data collection station, consisting of the steps of:</p> <p>programming each audience member's station with specific data of its audience member,</p> <p>programming each audience member station to process audience member response information input and assemble in a predetermined fashion or fashions record information that includes additional information besides said response information input, expressing a statement that prompts audience members to input response information, and causing at least one audience member to input response information</p> <p>thereby to cause said audience member's station to process said member's response information, assemble record information that includes additional data besides said response information, and transmit said additional data to said data collection station.</p>

Application Claim 75	U.S. Pat. No. 5,233,654, Claim 6
<p>75. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote</p>	<p>6. A method for collecting audience information in a system that consists of a plurality of audience member stations and at least one data collection station, each audience member station accommodating a specific audience member and having read/write memory means capable of holding specific data of its audience member, input means for inputting information of its audience member, first storage means for holding its audience member's input, processor means for processing its audience member's input and</p>

<p>transmitter station, <u>said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image</u>, said method comprising the steps of:</p> <p style="padding-left: 20px;"><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image</u>, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</p> <p style="padding-left: 20px;">transferring said downloadable processor instructions to a transmitter;</p> <p style="padding-left: 20px;">receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</p> <p style="padding-left: 20px;">transferring said at least one control signal to said transmitter; and</p> <p style="padding-left: 20px;">transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	<p>assembling output records that hold additional information besides said input, second storage means for holding said output records, and transmission means for transferring the output of said second storage means, with at least some of said stations programmed to process input information in a predetermined fashion and to transfer associated record information to a data collection station, consisting of the steps of:</p> <p style="padding-left: 20px;">programming each audience member's station with specific data of its audience member,</p> <p style="padding-left: 20px;">programming each audience member station to process audience member response information input and assemble in a predetermined fashion or fashions record information that includes additional information besides said response information input, expressing a statement that prompts audience members to input response information, and causing at least one audience member to input response information</p> <p style="padding-left: 20px;">thereby to cause said audience member's station to process said member's response information, assemble record information that includes additional data besides said response information, and transmit said additional data to said data collection station.</p>
---	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 80	U.S. Pat. No. 5,233,654, Claim 6
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u></p> <p style="padding-left: 20px;">receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</p> <p style="padding-left: 20px;"><u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video</u></p>	<p>6. A method for collecting audience information in a system that consists of a plurality of audience member stations and at least one data collection station, each audience member station accommodating a specific audience member and having read/write memory means capable of holding specific data of its audience member, input means for inputting information of its audience member, first storage means for holding its audience member's input, processor means for processing its audience member's input and assembling output records that hold additional information besides said input, second storage means for holding said output records, and transmission means for transferring the output of said second storage means, with at least some of said stations</p>

<p><u>presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u></p> <p>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</p> <p>transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>programmed to process input information in a predetermined fashion and to transfer associated record information to a data collection station, consisting of the steps of:</p> <p style="padding-left: 20px;">programming each audience member's station with specific data of its audience member,</p> <p style="padding-left: 20px;">programming each audience member station to process audience member response information input and assemble in a predetermined fashion or fashions record information that includes additional information besides said response information input, expressing a statement that prompts audience members to input response information, and causing at least one audience member to input response information</p> <p style="padding-left: 20px;">thereby to cause said audience member's station to process said member's response information, assemble record information that includes additional data besides said response information, and transmit said additional data to said data collection station.</p>
---	--

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 84	U.S. Pat. No. 5,233,654, Claim 6
<p>84. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, <u>wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals</u> and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <p style="padding-left: 20px;">receiving video at a transmitter station;</p> <p style="padding-left: 20px;">delivering said video to a transmitter;</p> <p style="padding-left: 20px;"><u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image</u></p>	<p>6. A method for collecting audience information in a system that consists of a plurality of audience member stations and at least one data collection station, each audience member station accommodating a specific audience member and having read/write memory means capable of holding specific data of its audience member, input means for inputting information of its audience member, first storage means for holding its audience member's input, processor means for processing its audience member's input and assembling output records that hold additional information besides said input, second storage means for holding said output records, and transmission means for transferring the output of said second storage means, with at least some of said stations programmed to process input information in a predetermined fashion and to transfer associated record information to a data collection station, consisting of the steps of:</p> <p style="padding-left: 20px;">programming each audience member's station with specific data of its audience member,</p> <p style="padding-left: 20px;">programming each audience member station to</p>

<p><u>for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and transmitting said video and said first discrete signal to said at least one receiver station.</p>	<p>process audience member response information input and assemble in a predetermined fashion or fashions record information that includes additional information besides said response information input, expressing a statement that prompts audience members to input response information, and causing at least one audience member to input response information thereby to cause said audience member's station to process said member's response information, assemble record information that includes additional data besides said response information, and transmit said additional data to said data collection station.</p>
--	---

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 93	U.S. Pat. No. 5,233,654, Claim 6
<p>93. A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <p>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal;</p> <p>detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission;</p> <p>passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor;</p> <p><u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to</u></p>	<p>6. A method for collecting audience information in a system that consists of a plurality of audience member stations and at least one data collection station, each audience member station accommodating a specific audience member and having read/write memory means capable of holding specific data of its audience member, input means for inputting information of its audience member, first storage means for holding its audience member's input, processor means for processing its audience member's input and assembling output records that hold additional information besides said input, second storage means for holding said output records, and transmission means for transferring the output of said second storage means, with at least some of said stations programmed to process input information in a predetermined fashion and to transfer associated record information to a data collection station, consisting of the steps of:</p> <p>programming each audience member's station with specific data of its audience member,</p> <p>programming each audience member station to process audience member response information input and assemble in a predetermined fashion or fashions record information that includes additional information besides said response information input, expressing a statement that prompts audience members to input response information, and causing at least one audience member to input</p>

<p><u>said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said</u> <u>video presentation containing, firstly, said video</u> <u>image and, secondly, said generated image to replace</u> <u>said only said portion of said video image.</u></p>	<p>response information thereby to cause said audience member's station to process said member's response information, assemble record information that includes additional data besides said response information, and transmit said additional data to said data collection station.</p>
---	---

Application Claim 110	U.S. Pat. No. 5,233,654, Claim 6
<p>110. <u>A method of outputting a video presentation</u> at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</p> <p><u>receiving at at least one transmitter station at least a</u> <u>first discrete signal containing information, wherein</u> <u>said at least one processor instruction comprises</u> <u>information organized from said information</u> <u>contained in said first discrete signal and information</u> <u>contained in a second discrete signal, said at least one</u> <u>processor instruction is effective at said at least one of</u> <u>said plurality of receiver stations to generate and</u> <u>output only a portion of said video presentation, said</u> <u>at least one processor instruction has at said at least</u> <u>one of said plurality of receiver stations a target</u> <u>processor to process data;</u></p> <p>transferring said at least said first discrete signal to at least one transmitter;</p> <p><u>receiving said at least one control signal at said at</u> <u>least one transmitter station, wherein said at least one</u> <u>control signal is operative at said at least one of said</u> <u>plurality of receiver stations to organize said</u> <u>information in said first and second discrete signals</u> <u>into said at least one processor instruction; and</u></p> <p>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>6. A method for collecting audience information in a system that consists of a plurality of audience member stations and at least one data collection station, each audience member station accommodating a specific audience member and having read/write memory means capable of holding specific data of its audience member, input means for inputting information of its audience member, first storage means for holding its audience member's input, processor means for processing its audience member's input and assembling output records that hold additional information besides said input, second storage means for holding said output records, and transmission means for transferring the output of said second storage means, with at least some of said stations programmed to process input information in a predetermined fashion and to transfer associated record information to a data collection station, consisting of the steps of:</p> <p>programming each audience member's station with specific data of its audience member,</p> <p>programming each audience member station to process audience member response information input and assemble in a predetermined fashion or fashions record information that includes additional information besides said response information input, expressing a statement that prompts audience members to input response information, and causing at least one audience member to input response information</p> <p>thereby to cause said audience member's station to process said member's response information, assemble record information that includes additional data besides said response information, and transmit said additional data to said data collection station.</p>

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 116	U.S. Pat. No. 5,233,654, Claim 6
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u></p> <p><u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u></p> <p>receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</p> <p>transferring said at least one control signal to said at least one origination transmitter before a specific time; and</p> <p>transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	<p>6. A method for collecting audience information in a system that consists of a plurality of audience member stations and at least one data collection station, each audience member station accommodating a specific audience member and having read/write memory means capable of holding specific data of its audience member, input means for inputting information of its audience member, first storage means for holding its audience member's input, processor means for processing its audience member's input and assembling output records that hold additional information besides said input, second storage means for holding said output records, and transmission means for transferring the output of said second storage means, with at least some of said stations programmed to process input information in a predetermined fashion and to transfer associated record information to a data collection station, consisting of the steps of:</p> <p>programming each audience member's station with specific data of its audience member,</p> <p>programming each audience member station to process audience member response information input and assemble in a predetermined fashion or fashions record information that includes additional information besides said response information input, expressing a statement that prompts audience members to input response information, and causing at least one audience member to input response information</p> <p>thereby to cause said audience member's station to process said member's response information, assemble record information that includes additional data besides said response information, and transmit said additional data to said data collection station.</p>

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 123	U.S. Pat. No. 5,233,654, Claim 6
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a</u></p>	<p>6. A method for collecting audience information in a system that consists of a plurality of audience member stations and at least one data collection station, each</p>

<p>processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p>transferring said at least one instruct signal to at least one transmitter;</p> <p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and</u></p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	<p>audience member station accommodating a specific audience member and having read/write memory means capable of holding specific data of its audience member, input means for inputting information of its audience member, first storage means for holding its audience member's input, processor means for processing its audience member's input and assembling output records that hold additional information besides said input, second storage means for holding said output records, and transmission means for transferring the output of said second storage means, with at least some of said stations programmed to process input information in a predetermined fashion and to transfer associated record information to a data collection station, consisting of the steps of:</p> <p>programming each audience member's station with specific data of its audience member,</p> <p>programming each audience member station to process audience member response information input and assemble in a predetermined fashion or fashions record information that includes additional information besides said response information input,</p> <p>expressing a statement that prompts audience members to input response information, and</p> <p>causing at least one audience member to input response information</p> <p>thereby to cause said audience member's station to process said member's response information, assemble record information that includes additional data besides said response information, and transmit said additional data to said data collection station.</p>
--	---

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 142	U.S. Pat. No. 5,233,654, Claim 6
-----------------------	----------------------------------

<p>142. A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p style="padding-left: 20px;">receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p style="padding-left: 20px;">detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p style="padding-left: 20px;">passing said detected at least a first discrete signal to at least one processor;</p> <p style="padding-left: 20px;"><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p style="padding-left: 20px;">passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p style="padding-left: 20px;">responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p style="padding-left: 20px;"><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u></p> <p style="padding-left: 20px;"><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>6. A method for collecting audience information in a system that consists of a plurality of audience member stations and at least one data collection station, each audience member station accommodating a specific audience member and having read/write memory means capable of holding specific data of its audience member, input means for inputting information of its audience member, first storage means for holding its audience member's input, processor means for processing its audience member's input and assembling output records that hold additional information besides said input, second storage means for holding said output records, and transmission means for transferring the output of said second storage means, with at least some of said stations programmed to process input information in a predetermined fashion and to transfer associated record information to a data collection station, consisting of the steps of:</p> <p style="padding-left: 20px;">programming each audience member's station with specific data of its audience member,</p> <p style="padding-left: 20px;">programming each audience member station to process audience member response information input and assemble in a predetermined fashion or fashions record information that includes additional information besides said response information input,</p> <p style="padding-left: 20px;">expressing a statement that prompts audience members to input response information, and</p> <p style="padding-left: 20px;">causing at least one audience member to input response information</p> <p style="padding-left: 20px;">thereby to cause said audience member's station to process said member's response information, assemble record information that includes additional data besides said response information, and transmit said additional data to said data collection station.</p>
--	---

Application Claim 143	U.S. Pat. No. 5,233,654, Claim 6
<p>143. A method of outputting a video presentation at a receiver station including:</p> <p style="padding-left: 20px;">receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal;</p> <p style="padding-left: 20px;">passing said received video image to an output device for delivery to a user;</p> <p style="padding-left: 20px;">detecting said at least one first discrete signal;</p> <p style="padding-left: 20px;">passing information contained in said at least one first discrete signal to a processor in response to said step of detecting;</p> <p style="padding-left: 20px;">organizing said information contained in said at</p>	<p>6. A method for collecting audience information in a system that consists of a plurality of audience member stations and at least one data collection station, each audience member station accommodating a specific audience member and having read/write memory means capable of holding specific data of its audience member, input means for inputting information of its audience member, first storage means for holding its audience member's input, processor means for processing its audience member's input and assembling output records that hold additional information besides said input, second storage means</p>

<p>least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</p> <p> responding, at said processor, to processor instructions comprising said organized information, based on said step of organizing;</p> <p> generating a signal based on said processor instructions; and</p> <p> outputting at least a portion of said video presentation based on said generated signal.</p>	<p>for holding said output records, and transmission means for transferring the output of said second storage means, with at least some of said stations programmed to process input information in a predetermined fashion and to transfer associated record information to a data collection station, consisting of the steps of:</p> <p> programming each audience member's station with specific data of its audience member,</p> <p> programming each audience member station to process audience member response information input and assemble in a predetermined fashion or fashions record information that includes additional information besides said response information input, expressing a statement that prompts audience members to input response information, and causing at least one audience member to input response information</p> <p> thereby to cause said audience member's station to process said member's response information, assemble record information that includes additional data besides said response information, and transmit said additional data to said data collection station.</p>
--	--

Application Claim 152	U.S. Pat. No. 5,233,654, Claim 6
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</u></p> <p> receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</p> <p> transferring said downloadable processor instructions to a transmitter;</p> <p> receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one</p>	<p>6. A method for collecting audience information in a system that consists of a plurality of audience member stations and at least one data collection station, each audience member station accommodating a specific audience member and having read/write memory means capable of holding specific data of its audience member, input means for inputting information of its audience member, first storage means for holding its audience member's input, processor means for processing its audience member's input and assembling output records that hold additional information besides said input, second storage means for holding said output records, and transmission means for transferring the output of said second storage means, with at least some of said stations programmed to process input information in a predetermined fashion and to transfer associated record information to a data collection station, consisting of the steps of:</p> <p> programming each audience member's station with specific data of its audience member,</p> <p> programming each audience member station to process audience member response information input and assemble in a predetermined fashion or fashions</p>

<p>receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and <u>wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>record information that includes additional information besides said response information input, expressing a statement that prompts audience members to input response information, and causing at least one audience member to input response information</p> <p>thereby to cause said audience member's station to process said member's response information, assemble record information that includes additional data besides said response information, and transmit said additional data to said data collection station.</p>
---	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 157	U.S. Pat. No. 5,233,654, Claim 6
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</p> <p>transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>6. A method for collecting audience information in a system that consists of a plurality of audience member stations and at least one data collection station, each audience member station accommodating a specific audience member and having read/write memory means capable of holding specific data of its audience member, input means for inputting information of its audience member, first storage means for holding its audience member's input, processor means for processing its audience member's input and assembling output records that hold additional information besides said input, second storage means for holding said output records, and transmission means for transferring the output of said second storage means, with at least some of said stations programmed to process input information in a predetermined fashion and to transfer associated record information to a data collection station, consisting of the steps of:</p> <p>programming each audience member's station with specific data of its audience member,</p> <p>programming each audience member station to process audience member response information input and assemble in a predetermined fashion or fashions record information that includes additional information besides said response information input, expressing a statement that prompts audience members to input response information, and</p>

	<p>causing at least one audience member to input response information</p> <p>thereby to cause said audience member's station to process said member's response information, assemble record information that includes additional data besides said response information, and transmit said additional data to said data collection station.</p>
--	---

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 162	U.S. Pat. No. 5,233,654, Claim 6
<p>162. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals</u>, said method comprising the steps of:</u></p> <p style="padding-left: 40px;">receiving a video image at a transmitter station; delivering said video image to a transmitter;</p> <p style="padding-left: 40px;"><u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u></p> <p style="padding-left: 40px;">transferring said at least said first of said plurality of discrete signals to said transmitter; and</p> <p style="padding-left: 40px;">transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>6. A method for collecting audience information in a system that consists of a plurality of audience member stations and at least one data collection station, each audience member station accommodating a specific audience member and having read/write memory means capable of holding specific data of its audience member, input means for inputting information of its audience member, first storage means for holding its audience member's input, processor means for processing its audience member's input and assembling output records that hold additional information besides said input, second storage means for holding said output records, and transmission means for transferring the output of said second storage means, with at least some of said stations programmed to process input information in a predetermined fashion and to transfer associated record information to a data collection station, consisting of the steps of:</p> <p style="padding-left: 40px;">programming each audience member's station with specific data of its audience member,</p> <p style="padding-left: 40px;">programming each audience member station to process audience member response information input and assemble in a predetermined fashion or fashions record information that includes additional information besides said response information input, expressing a statement that prompts audience members to input response information, and</p> <p style="padding-left: 40px;">causing at least one audience member to input response information</p> <p style="padding-left: 40px;">thereby to cause said audience member's station to process said member's response information, assemble record information that includes additional data besides said response information, and transmit said additional data to said data collection station.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 167	U.S. Pat. No. 5,233,654, Claim 6
<p>167. A method of outputting a video graphic presentation at a receiver station including:</p> <ul style="list-style-type: none"> receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image; passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen; displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen; detecting said at least a first discrete signal of said downloadable code; passing said at least a first discrete signal of said downloadable code to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> wherein said method delivers said video graphic presentation. 	<p>6. A method for collecting audience information in a system that consists of a plurality of audience member stations and at least one data collection station, each audience member station accommodating a specific audience member and having read/write memory means capable of holding specific data of its audience member, input means for inputting information of its audience member, first storage means for holding its audience member's input, processor means for processing its audience member's input and assembling output records that hold additional information besides said input, second storage means for holding said output records, and transmission means for transferring the output of said second storage means, with at least some of said stations programmed to process input information in a predetermined fashion and to transfer associated record information to a data collection station, consisting of the steps of:</p> <ul style="list-style-type: none"> programming each audience member's station with specific data of its audience member, programming each audience member station to process audience member response information input and assemble in a predetermined fashion or fashions record information that includes additional information besides said response information input, expressing a statement that prompts audience members to input response information, and causing at least one audience member to input response information <p>thereby to cause said audience member's station to process said member's response information, assemble record information that includes additional data besides said response information, and transmit said additional data to said data collection station.</p>

Application Claim 171	U.S. Pat. No. 5,233,654, Claim 6
<p>171. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:</u></p> <p><u>receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</u></p> <p><u>transferring said at least one discrete signal to a transmitter;</u></p> <p><u>receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;</u></p> <p><u>transferring said one or more control signals to said transmitter; and</u></p> <p><u>transmitting a transmission comprising said at least</u></p>	<p>6. A method for collecting audience information in a system that consists of a plurality of audience member stations and at least one data collection station, each audience member station accommodating a specific audience member and having read/write memory means capable of holding specific data of its audience member, input means for inputting information of its audience member, first storage means for holding its audience member's input, processor means for processing its audience member's input and assembling output records that hold additional information besides said input, second storage means for holding said output records, and transmission means for transferring the output of said second storage means, with at least some of said stations programmed to process input information in a predetermined fashion and to transfer associated record information to a data collection station, consisting of the steps of:</p> <p>programming each audience member's station with specific data of its audience member,</p> <p>programming each audience member station to process audience member response information input and assemble in a predetermined fashion or fashions record information that includes additional information besides said response information input,</p> <p>expressing a statement that prompts audience members to input response information, and</p> <p>causing at least one audience member to input response information</p> <p>thereby to cause said audience member's station to process said member's response information, assemble record information that includes additional data besides said response information, and transmit said additional data to said data collection station.</p>

<p>one discrete signal and said one or more control signals, wherein said method delivers said video graphic presentation.</p>	
--	--

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 175	U.S. Pat. No. 5,233,654, Claim 6
<p>175. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one</p>	<p>6. A method for collecting audience information in a system that consists of a plurality of audience member stations and at least one data collection station, each audience member station accommodating a specific audience member and having read/write memory means capable of holding specific data of its audience member, input means for inputting information of its audience member, first storage means for holding its audience member's input, processor means for processing its audience member's input and assembling output records that hold additional information besides said input, second storage means for holding said output records, and transmission means for transferring the output of said second storage means, with at least some of said stations programmed to process input information in a predetermined fashion and to transfer associated record information to a data collection station, consisting of the steps of:</p> <p>programming each audience member's station with specific data of its audience member,</p> <p>programming each audience member station to process audience member response information input and assemble in a predetermined fashion or fashions record information that includes additional information besides said response information input, expressing a statement that prompts audience members to input response information, and causing at least one audience member to input response information</p> <p>thereby to cause said audience member's station to process said member's response information, assemble record information that includes additional data besides said response information, and transmit said additional data to said data collection station.</p>

<p>processor instruction, and said second completed full-screen video graphic image; and</p> <p>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</p> <p>wherein said method delivers said video graphic presentation.</p>	
---	--

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 177	U.S. Pat. No. 5,233,654, Claim 6
<p>177. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>transferring said one or more instruct signals to said transmitter; and</p>	<p>6. A method for collecting audience information in a system that consists of a plurality of audience member stations and at least one data collection station, each audience member station accommodating a specific audience member and having read/write memory means capable of holding specific data of its audience member, input means for inputting information of its audience member, first storage means for holding its audience member's input, processor means for processing its audience member's input and assembling output records that hold additional information besides said input, second storage means for holding said output records, and transmission means for transferring the output of said second storage means, with at least some of said stations programmed to process input information in a predetermined fashion and to transfer associated record information to a data collection station, consisting of the steps of:</p> <p>programming each audience member's station with specific data of its audience member,</p> <p>programming each audience member station to process audience member response information input and assemble in a predetermined fashion or fashions record information that includes additional information besides said response information input, expressing a statement that prompts audience members to input response information, and causing at least one audience member to input response information</p> <p>thereby to cause said audience member's station to process said member's response information, assemble record information that includes additional data besides said response information, and transmit</p>

transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station, wherein said method delivers said video graphic presentation.	said additional data to said data collection station.
---	---

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 179	U.S. Pat. No. 5,233,654, Claim 6
<p>179. A method of outputting a video graphic presentation at a receiver station including:</p> <ul style="list-style-type: none"> receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image; passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen; displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen; detecting said at least a first discrete signal; passing said at least a first discrete signal to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image;</u> and <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen</u> 	<p>6. A method for collecting audience information in a system that consists of a plurality of audience member stations and at least one data collection station, each audience member station accommodating a specific audience member and having read/write memory means capable of holding specific data of its audience member, input means for inputting information of its audience member, first storage means for holding its audience member's input, processor means for processing its audience member's input and assembling output records that hold additional information besides said input, second storage means for holding said output records, and transmission means for transferring the output of said second storage means, with at least some of said stations programmed to process input information in a predetermined fashion and to transfer associated record information to a data collection station, consisting of the steps of:</p> <ul style="list-style-type: none"> programming each audience member's station with specific data of its audience member, programming each audience member station to process audience member response information input and assemble in a predetermined fashion or fashions record information that includes additional information besides said response information input, expressing a statement that prompts audience members to input response information, and causing at least one audience member to input response information <p>thereby to cause said audience member's station to process said member's response information, assemble record information that includes additional data besides said response information, and transmit said additional data to said data collection station.</p>

<u>video graphic image,</u> wherein said method delivers said video graphic presentation.

Application Claim 56	U.S. Pat. No. 5,233,654, Claim 7
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p>and</p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>7. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising</p> <p>input means for inputting member information,</p> <p>first memory means for storing said input information,</p> <p>detector means for detecting in a broadcast transmission at least one instruction,</p> <p>processor means operatively connected to said first memory means and said detector means for processing said input information in accordance with said instruction and outputting data that include additional information besides said input information,</p> <p>second memory means for storing said data, and</p> <p>transmission means for transmitting said data to said data collection station.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 5,233,654, Claim 7
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable</u></p>	<p>7. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising</p> <p>input means for inputting member information,</p> <p>first memory means for storing said input information,</p> <p>detector means for detecting in a broadcast transmission at least one instruction,</p> <p>processor means operatively connected to said first memory means and said detector means for processing said input information in accordance with said instruction and outputting data that include additional information besides said input information,</p> <p>second memory means for storing said data, and</p> <p>transmission means for transmitting said data to said data collection station.</p>

<p>processor instructions having at said at least one receiver station a target processor to process data; transferring said downloadable processor instructions to a transmitter; receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation; transferring said at least one control signal to said transmitter; and transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	
---	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 5,233,654, Claim 7
<p>80. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of: receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station; <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>7. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising input means for inputting member information, first memory means for storing said input information, detector means for detecting in a broadcast transmission at least one instruction, processor means operatively connected to said first memory means and said detector means for processing said input information in accordance with said instruction and outputting data that include additional information besides said input information, second memory means for storing said data, and transmission means for transmitting said data to said data collection station.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 5,233,654, Claim 7
<p>84. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, <u>wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals</u> and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving video at a transmitter station; delivering said video to a transmitter; <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and transmitting said video and said first discrete signal to said at least one receiver station. 	<p>7. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising</p> <ul style="list-style-type: none"> input means for inputting member information, first memory means for storing said input information, detector means for detecting in a broadcast transmission at least one instruction, processor means operatively connected to said first memory means and said detector means for processing said input information in accordance with said instruction and outputting data that include additional information besides said input information, second memory means for storing said data, and transmission means for transmitting said data to said data collection station.

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 5,233,654, Claim 7
<p>93. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete 	<p>7. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising</p> <ul style="list-style-type: none"> input means for inputting member information, first memory means for storing said input information, detector means for detecting in a broadcast

<p>signal and at least one control signal; detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission; passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor; <u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; <u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>transmission at least one instruction, processor means operatively connected to said first memory means and said detector means for processing said input information in accordance with said instruction and outputting data that include additional information besides said input information, second memory means for storing said data, and transmission means for transmitting said data to said data collection station.</p>
--	---

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 5,233,654, Claim 7
<p>110. <u>A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</u> <u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said</u></p>	<p>7. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising input means for inputting member information, first memory means for storing said input information, detector means for detecting in a broadcast transmission at least one instruction, processor means operatively connected to said first memory means and said detector means for processing said input information in accordance with said instruction and outputting data that include additional information besides said input information, second memory means for storing said data, and transmission means for transmitting said data to said data collection station.</p>

at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;
transferring said at least said first discrete signal to at least one transmitter;
receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and
transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 5,233,654, Claim 7
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u> <u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u> receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction; transferring said at least one control signal to said at</p>	<p>7. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising input means for inputting member information, first memory means for storing said input information, detector means for detecting in a broadcast transmission at least one instruction, processor means operatively connected to said first memory means and said detector means for processing said input information in accordance with said instruction and outputting data that include additional information besides said input information, second memory means for storing said data, and transmission means for transmitting said data to said data collection station.</p>

<p>least one origination transmitter before a specific time; and transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	
---	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 5,233,654, Claim 7
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u> <u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u> transferring said at least one instruct signal to at least one transmitter; <u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to</u></p>	<p>7. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising input means for inputting member information, first memory means for storing said input information, detector means for detecting in a broadcast transmission at least one instruction, processor means operatively connected to said first memory means and said detector means for processing said input information in accordance with said instruction and outputting data that include additional information besides said input information, second memory means for storing said data, and transmission means for transmitting said data to said data collection station.</p>

<p>be effective at said at least one of said plurality of receiver stations; and</p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	
---	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 5,233,654, Claim 7
<p>142. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction;</u> and</p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>7. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising</p> <p>input means for inputting member information,</p> <p>first memory means for storing said input information,</p> <p>detector means for detecting in a broadcast transmission at least one instruction,</p> <p>processor means operatively connected to said first memory means and said detector means for processing said input information in accordance with said instruction and outputting data that include additional information besides said input information,</p> <p>second memory means for storing said data, and</p> <p>transmission means for transmitting said data to said data collection station.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 5,233,654, Claim 7
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u> receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to <u>processor instructions comprising said organized information,</u> based on said step of organizing; generating a signal based on said processor instructions; and outputting at least a portion of said video presentation based on said generated signal.</p>	<p>7. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising input means for inputting member information, first memory means for storing said input information, detector means for detecting in a broadcast transmission at least one instruction, processor means operatively connected to said first memory means and said detector means for processing said input information in accordance with said instruction and outputting data that include additional information besides said input information, second memory means for storing said data, and transmission means for transmitting said data to said data collection station.</p>

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 5,233,654, Claim 7
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station,</u> said method comprising the steps of: receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions; transferring said downloadable processor</p>	<p>7. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising input means for inputting member information, first memory means for storing said input information, detector means for detecting in a broadcast transmission at least one instruction, processor means operatively connected to said first memory means and said detector means for processing said input information in accordance with said instruction and outputting data that include additional information besides said input information, second memory means for storing said data, and transmission means for transmitting said data to said data collection station.</p>

<p>instructions to a transmitter; <u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u> transferring said one or more control signals to said transmitter; and transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	
--	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 5,233,654, Claim 7
<p>157. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of: receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station; <u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u> receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>7. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising input means for inputting member information, first memory means for storing said input information, detector means for detecting in a broadcast transmission at least one instruction, processor means operatively connected to said first memory means and said detector means for processing said input information in accordance with said instruction and outputting data that include additional information besides said input information, second memory means for storing said data, and transmission means for transmitting said data to said data collection station.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 5,233,654, Claim 7
<p>162. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals</u>, said method comprising the steps of:</p> <p>receiving a video image at a transmitter station; delivering said video image to a transmitter; <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> transferring said at least said first of said plurality of discrete signals to said transmitter; and transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>7. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising</p> <p>input means for inputting member information, first memory means for storing said input information, detector means for detecting in a broadcast transmission at least one instruction, processor means operatively connected to said first memory means and said detector means for processing said input information in accordance with said instruction and outputting data that include additional information besides said input information, second memory means for storing said data, and transmission means for transmitting said data to said data collection station.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus.

Application Claim 167	U.S. Pat. No. 5,233,654, Claim 7
<p>167. <u>A method of outputting a video graphic presentation</u> at a receiver station including:</p> <p>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-</p>	<p>7. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising</p> <p>input means for inputting member information,</p>

<p>screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</p> <p>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal of said downloadable code;</p> <p>passing said at least a first discrete signal of said downloadable code to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u></p> <p><u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u></p> <p>wherein said method delivers said video graphic presentation.</p>	<p>first memory means for storing said input information,</p> <p>detector means for detecting in a broadcast transmission at least one instruction,</p> <p>processor means operatively connected to said first memory means and said detector means for processing said input information in accordance with said instruction and outputting data that include additional information besides said input information,</p> <p>second memory means for storing said data, and</p> <p>transmission means for transmitting said data to said data collection station.</p>
--	---

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 5,233,654, Claim 7
<p>171. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is</p>	<p>7. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising</p> <p style="padding-left: 40px;">input means for inputting member information,</p> <p style="padding-left: 40px;">first memory means for storing said input information,</p>

programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;

transferring said at least one discrete signal to a transmitter;

receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said at least one discrete signal and said one or more control signals,

wherein said method delivers said video graphic presentation.

detector means for detecting in a broadcast transmission at least one instruction,

processor means operatively connected to said first memory means and said detector means for processing said input information in accordance with said instruction and outputting data that include additional information besides said input information,

second memory means for storing said data, and
transmission means for transmitting said data to said data collection station.

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 5,233,654, Claim 7
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u></p> <p style="padding-left: 2em;">receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</p> <p style="padding-left: 2em;"><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p style="padding-left: 2em;">receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</p> <p style="padding-left: 2em;">transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</p> <p style="padding-left: 2em;">wherein said method delivers said video graphic presentation.</p>	<p>7. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising</p> <p style="padding-left: 2em;">input means for inputting member information, first memory means for storing said input information,</p> <p style="padding-left: 2em;">detector means for detecting in a broadcast transmission at least one instruction,</p> <p style="padding-left: 2em;">processor means operatively connected to said first memory means and said detector means for processing said input information in accordance with said instruction and outputting data that include additional information besides said input information,</p> <p style="padding-left: 2em;">second memory means for storing said data, and</p> <p style="padding-left: 2em;">transmission means for transmitting said data to said data collection station.</p>

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 5,233,654, Claim 7
<p>177. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>transferring said one or more instruct signals to said transmitter; and</p> <p>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>7. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising</p> <p>input means for inputting member information,</p> <p>first memory means for storing said input information,</p> <p>detector means for detecting in a broadcast transmission at least one instruction,</p> <p>processor means operatively connected to said first memory means and said detector means for processing said input information in accordance with said instruction and outputting data that include additional information besides said input information,</p> <p>second memory means for storing said data, and</p> <p>transmission means for transmitting said data to said data collection station.</p>

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 5,233,654, Claim 7
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u></p> <p>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</p> <p>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal;</p> <p>passing said at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u></p> <p><u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u></p> <p>wherein said method delivers said video graphic presentation.</p>	<p>7. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising</p> <p>input means for inputting member information,</p> <p>first memory means for storing said input information,</p> <p>detector means for detecting in a broadcast transmission at least one instruction,</p> <p>processor means operatively connected to said first memory means and said detector means for processing said input information in accordance with said instruction and outputting data that include additional information besides said input information,</p> <p>second memory means for storing said data, and</p> <p>transmission means for transmitting said data to said data collection station.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus.

This Page Blank (uspto)

Application Claim 56	U.S. Pat. No. 5,233,654, Claim 10
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p>and</p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>10. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising</p> <p>input means for inputting member information,</p> <p>first memory means for storing said input information,</p> <p>detector means for detecting in a broadcast transmission at least one datum,</p> <p>processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and outputting data that include additional information besides said input information,</p> <p>second memory means for storing said data, and</p> <p>transmission means for transmitting said data to said data collection station.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 5,233,654, Claim 10
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable</u></p>	<p>10. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising</p> <p>input means for inputting member information,</p> <p>first memory means for storing said input information,</p> <p>detector means for detecting in a broadcast transmission at least one datum,</p> <p>processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and outputting data that include additional information besides said input information,</p> <p>second memory means for storing said data, and</p> <p>transmission means for transmitting said data to said data collection station.</p>

<p>processor instructions having at said at least one receiver station a target processor to process data; transferring said downloadable processor instructions to a transmitter; receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation; transferring said at least one control signal to said transmitter; and transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	
---	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 5,233,654, Claim 10
<p>80. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of: receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station; <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>10. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising input means for inputting member information, first memory means for storing said input information, detector means for detecting in a broadcast transmission at least one datum, processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and outputting data that include additional information besides said input information, second memory means for storing said data, and transmission means for transmitting said data to said data collection station.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 5,233,654, Claim 10
<p>84. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, <u>wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals</u> and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving video at a transmitter station; delivering said video to a transmitter; <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and transmitting said video and said first discrete signal to said at least one receiver station. 	<p>10. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising</p> <ul style="list-style-type: none"> input means for inputting member information, first memory means for storing said input information, detector means for detecting in a broadcast transmission at least one datum, processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and outputting data that include additional information besides said input information, second memory means for storing said data, and transmission means for transmitting said data to said data collection station.

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 5,233,654, Claim 10
<p>93. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete 	<p>10. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising</p> <ul style="list-style-type: none"> input means for inputting member information, first memory means for storing said input information, detector means for detecting in a broadcast

<p>signal and at least one control signal; detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission; passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor; <u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; <u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>transmission at least one datum, processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and outputting data that include additional information besides said input information, second memory means for storing said data, and transmission means for transmitting said data to said data collection station.</p>
--	--

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 5,233,654, Claim 10
<p>110. A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of: <u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said</u></p>	<p>10. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising input means for inputting member information, first memory means for storing said input information, detector means for detecting in a broadcast transmission at least one datum, processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and outputting data that include additional information besides said input information, second memory means for storing said data, and transmission means for transmitting said data to said data collection station.</p>

at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;
transferring said at least said first discrete signal to at least one transmitter;
receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and
transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 5,233,654, Claim 10
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u> receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal; receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction; transferring said at least one control signal to said at</p>	<p>10. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising input means for inputting member information, first memory means for storing said input information, detector means for detecting in a broadcast transmission at least one datum, processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and outputting data that include additional information besides said input information, second memory means for storing said data, and transmission means for transmitting said data to said data collection station.</p>

<p>least one origination transmitter before a specific time; and transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	
---	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 5,233,654, Claim 10
<p>123. <u>A method of delivering a video presentation</u> at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p>transferring said at least one instruct signal to at least one transmitter;</p> <p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to</u></p>	<p>10. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising</p> <p>input means for inputting member information,</p> <p>first memory means for storing said input information,</p> <p>detector means for detecting in a broadcast transmission at least one datum,</p> <p>processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and outputting data that include additional information besides said input information,</p> <p>second memory means for storing said data, and</p> <p>transmission means for transmitting said data to said data collection station.</p>

<p>be effective at said at least one of said plurality of receiver stations; and</p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	
---	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 5,233,654, Claim 10
<p>142. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>10. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising</p> <p>input means for inputting member information,</p> <p>first memory means for storing said input information,</p> <p>detector means for detecting in a broadcast transmission at least one datum,</p> <p>processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and outputting data that include additional information besides said input information,</p> <p>second memory means for storing said data, and</p> <p>transmission means for transmitting said data to said data collection station.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 5,233,654, Claim 10
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u></p> <ul style="list-style-type: none"> receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to <u>processor instructions comprising said organized information,</u> based on said step of organizing; generating a signal based on said processor instructions; and outputting at least a portion of said video presentation based on said generated signal. 	<p>10. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising</p> <ul style="list-style-type: none"> input means for inputting member information, first memory means for storing said input information, detector means for detecting in a broadcast transmission at least one datum, processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and outputting data that include additional information besides said input information, second memory means for storing said data, and transmission means for transmitting said data to said data collection station.

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 5,233,654, Claim 10
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station,</u> said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions; transferring said downloadable processor 	<p>10. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising</p> <ul style="list-style-type: none"> input means for inputting member information, first memory means for storing said input information, detector means for detecting in a broadcast transmission at least one datum, processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and outputting data that include additional information besides said input information, second memory means for storing said data, and transmission means for transmitting said data to said data collection station.

<p>instructions to a transmitter;</p> <p><u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	
--	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 5,233,654, Claim 10
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</p> <p>transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>10. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising</p> <p>input means for inputting member information,</p> <p>first memory means for storing said input information,</p> <p>detector means for detecting in a broadcast transmission at least one datum,</p> <p>processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and outputting data that include additional information besides said input information,</p> <p>second memory means for storing said data, and</p> <p>transmission means for transmitting said data to said data collection station.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 5,233,654, Claim 10
<p>162. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals</u>, said method comprising the steps of:</p> <p style="padding-left: 40px;">receiving a video image at a transmitter station; delivering said video image to a transmitter; <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> transferring said at least said first of said plurality of discrete signals to said transmitter; and transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>10. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising</p> <p style="padding-left: 40px;">input means for inputting member information, first memory means for storing said input information, detector means for detecting in a broadcast transmission at least one datum, processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and outputting data that include additional information besides said input information, second memory means for storing said data, and transmission means for transmitting said data to said data collection station.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus.

Application Claim 167	U.S. Pat. No. 5,233,654, Claim 10
<p>167. <u>A method of outputting a video graphic presentation</u> at a receiver station including:</p> <p style="padding-left: 40px;">receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-</p>	<p>10. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising</p> <p style="padding-left: 40px;">input means for inputting member information,</p>

<p>screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</p> <p>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal of said downloadable code;</p> <p>passing said at least a first discrete signal of said downloadable code to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u></p> <p><u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u></p> <p>wherein said method delivers said video graphic presentation.</p>	<p>first memory means for storing said input information,</p> <p>detector means for detecting in a broadcast transmission at least one datum,</p> <p>processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and outputting data that include additional information besides said input information,</p> <p>second memory means for storing said data, and</p> <p>transmission means for transmitting said data to said data collection station.</p>
--	--

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 5,233,654, Claim 10
<p>171. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is</p>	<p>10. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising</p> <p>input means for inputting member information,</p> <p>first memory means for storing said input information,</p>

programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;

transferring said at least one discrete signal to a transmitter;

receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said at least one discrete signal and said one or more control signals,

wherein said method delivers said video graphic presentation.

detector means for detecting in a broadcast transmission at least one datum,

processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and outputting data that include additional information besides said input information,

second memory means for storing said data, and
transmission means for transmitting said data to said data collection station.

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 5,233,654, Claim 10
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u></p> <p style="padding-left: 40px;">receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</p> <p style="padding-left: 40px;"><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p style="padding-left: 40px;">receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</p> <p style="padding-left: 40px;">transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</p> <p style="padding-left: 40px;">wherein said method delivers said video graphic presentation.</p>	<p>10. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising</p> <p style="padding-left: 40px;">input means for inputting member information,</p> <p style="padding-left: 40px;">first memory means for storing said input information,</p> <p style="padding-left: 40px;">detector means for detecting in a broadcast transmission at least one datum,</p> <p style="padding-left: 40px;">processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and outputting data that include additional information besides said input information,</p> <p style="padding-left: 40px;">second memory means for storing said data, and</p> <p style="padding-left: 40px;">transmission means for transmitting said data to said data collection station.</p>

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 5,233,654, Claim 10
<p>177. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>transferring said one or more instruct signals to said transmitter; and</p> <p>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>10. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising</p> <p>input means for inputting member information,</p> <p>first memory means for storing said input information,</p> <p>detector means for detecting in a broadcast transmission at least one datum,</p> <p>processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and outputting data that include additional information besides said input information,</p> <p>second memory means for storing said data, and</p> <p>transmission means for transmitting said data to said data collection station.</p>

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 5,233,654, Claim 10
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u> receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image; passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen; displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen; detecting said at least a first discrete signal; passing said at least a first discrete signal to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> wherein said method delivers said video graphic presentation.</p>	<p>10. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising input means for inputting member information, first memory means for storing said input information, detector means for detecting in a broadcast transmission at least one datum, processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and outputting data that include additional information besides said input information, second memory means for storing said data, and transmission means for transmitting said data to said data collection station.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus.

This Page Blank (uspto)

Application Claim 56	U.S. Pat. No. 5,233,654, Claim 13
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p>and</p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>13. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising</p> <p>first memory means for storing first information of said member,</p> <p>detector means for detecting in a broadcast transmission at least one instruction,</p> <p>first processor means operatively connected to said first memory means and said detector means for processing said first information and outputting data that include additional information besides said first information,</p> <p>second memory means for storing said data,</p> <p>transmission means for transmitting said data to said data collection station, and</p> <p>second processor means operatively connected to said transmission means and said detector means for causing said transmission means to transmit said additional information in response to said instruction.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 5,233,654, Claim 13
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable</u></p>	<p>13. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising</p> <p>first memory means for storing first information of said member,</p> <p>detector means for detecting in a broadcast transmission at least one instruction,</p> <p>first processor means operatively connected to said first memory means and said detector means for processing said first information and outputting data that include additional information besides said first information,</p> <p>second memory means for storing said data,</p> <p>transmission means for transmitting said data to said data collection station, and</p> <p>second processor means operatively connected to said transmission means and said detector means for causing said transmission means to transmit said additional information in response to said instruction.</p>

<p>processor instructions having at said at least one receiver station a target processor to process data; transferring said downloadable processor instructions to a transmitter; receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation; transferring said at least one control signal to said transmitter; and transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	
---	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 5,233,654, Claim 13
<p>80. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of: receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station; <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>13. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising first memory means for storing first information of said member, detector means for detecting in a broadcast transmission at least one instruction, first processor means operatively connected to said first memory means and said detector means for processing said first information and outputting data that include additional information besides said first information, second memory means for storing said data, transmission means for transmitting said data to said data collection station, and second processor means operatively connected to said transmission means and said detector means for causing said transmission means to transmit said additional information in response to said instruction.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 5,233,654, Claim 13
<p>84. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, <u>wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals</u> and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving video at a transmitter station; delivering said video to a transmitter; <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and transmitting said video and said first discrete signal to said at least one receiver station. 	<p>13. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising</p> <ul style="list-style-type: none"> first memory means for storing first information of said member, detector means for detecting in a broadcast transmission at least one instruction, first processor means operatively connected to said first memory means and said detector means for processing said first information and outputting data that include additional information besides said first information, second memory means for storing said data, transmission means for transmitting said data to said data collection station, and second processor means operatively connected to said transmission means and said detector means for causing said transmission means to transmit said additional information in response to said instruction.

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 5,233,654, Claim 13
<p>93. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete 	<p>13. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising</p> <ul style="list-style-type: none"> first memory means for storing first information of said member, detector means for detecting in a broadcast transmission at least one instruction,

<p>signal and at least one control signal; detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission; passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor; <u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; <u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>first processor means operatively connected to said first memory means and said detector means for processing said first information and outputting data that include additional information besides said first information, second memory means for storing said data, transmission means for transmitting said data to said data collection station, and second processor means operatively connected to said transmission means and said detector means for causing said transmission means to transmit said additional information in response to said instruction.</p>
--	---

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 5,233,654, Claim 13
<p>110. <u>A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</u> <u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said</u></p>	<p>13. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising first memory means for storing first information of said member, detector means for detecting in a broadcast transmission at least one instruction, first processor means operatively connected to said first memory means and said detector means for processing said first information and outputting data that include additional information besides said first information, second memory means for storing said data, transmission means for transmitting said data to said data collection station, and second processor means operatively connected to</p>

<p><u>at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u> transferring said at least said first discrete signal to at least one transmitter; receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>said transmission means and said detector means for causing said transmission means to transmit said additional information in response to said instruction.</p>
---	---

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 5,233,654, Claim 13
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction,</u> said method comprising the steps of: <u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u> receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction; transferring said at least one control signal to said at</p>	<p>13. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising first memory means for storing first information of said member, detector means for detecting in a broadcast transmission at least one instruction, first processor means operatively connected to said first memory means and said detector means for processing said first information and outputting data that include additional information besides said first information, second memory means for storing said data, transmission means for transmitting said data to said data collection station, and second processor means operatively connected to said transmission means and said detector means for causing said transmission means to transmit said additional information in response to said instruction.</p>

<p>least one origination transmitter before a specific time; and transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	
---	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 5,233,654, Claim 13
<p>123. A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p>transferring said at least one instruct signal to at least one transmitter;</p> <p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to</u></p>	<p>13. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising</p> <p>first memory means for storing first information of said member,</p> <p>detector means for detecting in a broadcast transmission at least one instruction,</p> <p>first processor means operatively connected to said first memory means and said detector means for processing said first information and outputting data that include additional information besides said first information,</p> <p>second memory means for storing said data,</p> <p>transmission means for transmitting said data to said data collection station, and</p> <p>second processor means operatively connected to said transmission means and said detector means for causing said transmission means to transmit said additional information in response to said instruction.</p>

<p>be effective at said at least one of said plurality of receiver stations; and</p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	
---	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 5,233,654, Claim 13
<p>142. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction;</u> and</p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>13. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising</p> <p>first memory means for storing first information of said member,</p> <p>detector means for detecting in a broadcast transmission at least one instruction,</p> <p>first processor means operatively connected to said first memory means and said detector means for processing said first information and outputting data that include additional information besides said first information,</p> <p>second memory means for storing said data,</p> <p>transmission means for transmitting said data to said data collection station, and</p> <p>second processor means operatively connected to said transmission means and said detector means for causing said transmission means to transmit said additional information in response to said instruction.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 5,233,654, Claim 13
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u> receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to <u>processor instructions comprising said organized information,</u> based on said step of organizing; generating a signal based on said processor instructions; and outputting at least a portion of said video presentation based on said generated signal.</p>	<p>13. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising first memory means for storing first information of said member, detector means for detecting in a broadcast transmission at least one instruction, first processor means operatively connected to said first memory means and said detector means for processing said first information and outputting data that include additional information besides said first information, second memory means for storing said data, transmission means for transmitting said data to said data collection station, and second processor means operatively connected to said transmission means and said detector means for causing said transmission means to transmit said additional information in response to said instruction.</p>

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 5,233,654, Claim 13
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</u> receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions; transferring said downloadable processor</p>	<p>13. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising first memory means for storing first information of said member, detector means for detecting in a broadcast transmission at least one instruction, first processor means operatively connected to said first memory means and said detector means for processing said first information and outputting data that include additional information besides said first information, second memory means for storing said data, transmission means for transmitting said data to said data collection station, and second processor means operatively connected to said transmission means and said detector means for causing said transmission means to transmit said</p>

<p>instructions to a transmitter; <u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u> transferring said one or more control signals to said transmitter; and transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>additional information in response to said instruction.</p>
--	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 5,233,654, Claim 13
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u> receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station; <u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u> receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>13. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising first memory means for storing first information of said member, detector means for detecting in a broadcast transmission at least one instruction, first processor means operatively connected to said first memory means and said detector means for processing said first information and outputting data that include additional information besides said first information, second memory means for storing said data, transmission means for transmitting said data to said data collection station, and second processor means operatively connected to said transmission means and said detector means for causing said transmission means to transmit said additional information in response to said instruction.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 5,233,654, Claim 13
<p>162. <u>A method of delivering a video presentation</u> at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals</u>, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving a video image at a transmitter station; delivering said video image to a transmitter; <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> transferring said at least said first of said plurality of discrete signals to said transmitter; and transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station. 	<p>13. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising</p> <ul style="list-style-type: none"> first memory means for storing first information of said member, detector means for detecting in a broadcast transmission at least one instruction, first processor means operatively connected to said first memory means and said detector means for processing said first information and outputting data that include additional information besides said first information, second memory means for storing said data, transmission means for transmitting said data to said data collection station, and second processor means operatively connected to said transmission means and said detector means for causing said transmission means to transmit said additional information in response to said instruction.

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus.

Application Claim 167	U.S. Pat. No. 5,233,654, Claim 13
<p>167. <u>A method of outputting a video graphic presentation</u> at a receiver station including:</p> <ul style="list-style-type: none"> receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full- 	<p>13. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising</p> <ul style="list-style-type: none"> first memory means for storing first information of

<p>screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</p> <p>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal of said downloadable code;</p> <p>passing said at least a first discrete signal of said downloadable code to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u></p> <p><u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u></p> <p>wherein said method delivers said video graphic presentation.</p>	<p>said member,</p> <p>detector means for detecting in a broadcast transmission at least one instruction,</p> <p>first processor means operatively connected to said first memory means and said detector means for processing said first information and outputting data that include additional information besides said first information,</p> <p>second memory means for storing said data,</p> <p>transmission means for transmitting said data to said data collection station, and</p> <p>second processor means operatively connected to said transmission means and said detector means for causing said transmission means to transmit said additional information in response to said instruction.</p>
--	---

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 5,233,654, Claim 13
171. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is	13. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising first memory means for storing first information of said member, detector means for detecting in a broadcast

programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;

transferring said at least one discrete signal to a transmitter;

receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said at least one discrete signal and said one or more control signals,

wherein said method delivers said video graphic presentation.

transmission at least one instruction,

first processor means operatively connected to said first memory means and said detector means for processing said first information and outputting data that include additional information besides said first information,

second memory means for storing said data, transmission means for transmitting said data to said data collection station, and

second processor means operatively connected to said transmission means and said detector means for causing said transmission means to transmit said additional information in response to said instruction.

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 5,233,654, Claim 13
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u></p> <p>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</p> <p>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>13. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising</p> <p>first memory means for storing first information of said member,</p> <p>detector means for detecting in a broadcast transmission at least one instruction,</p> <p>first processor means operatively connected to said first memory means and said detector means for processing said first information and outputting data that include additional information besides said first information,</p> <p>second memory means for storing said data, transmission means for transmitting said data to said data collection station, and</p> <p>second processor means operatively connected to said transmission means and said detector means for causing said transmission means to transmit said additional information in response to said instruction.</p>

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 5,233,654, Claim 13
<p>177. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>transferring said one or more instruct signals to said transmitter; and</p> <p>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>13. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising</p> <p>first memory means for storing first information of said member,</p> <p>detector means for detecting in a broadcast transmission at least one instruction,</p> <p>first processor means operatively connected to said first memory means and said detector means for processing said first information and outputting data that include additional information besides said first information,</p> <p>second memory means for storing said data,</p> <p>transmission means for transmitting said data to said data collection station, and</p> <p>second processor means operatively connected to said transmission means and said detector means for causing said transmission means to transmit said additional information in response to said instruction.</p>

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 5,233,654, Claim 13
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u></p> <p>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</p> <p>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal;</p> <p>passing said at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u></p> <p><u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u></p> <p>wherein said method delivers said video graphic presentation.</p>	<p>13. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising</p> <p>first memory means for storing first information of said member,</p> <p>detector means for detecting in a broadcast transmission at least one instruction,</p> <p>first processor means operatively connected to said first memory means and said detector means for processing said first information and outputting data that include additional information besides said first information,</p> <p>second memory means for storing said data,</p> <p>transmission means for transmitting said data to said data collection station, and</p> <p>second processor means operatively connected to said transmission means and said detector means for causing said transmission means to transmit said additional information in response to said instruction.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus.

Application Claim 56	U.S. Pat. No. 5,233,654, Claim 16
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p>and</p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>16. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising</p> <p>input means for inputting member information,</p> <p>first memory means for storing said input information,</p> <p>detector means for detecting in a broadcast transmission at least one datum,</p> <p>first processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and outputting data that include additional information besides said input information,</p> <p>second memory means for storing said data,</p> <p>transmission means for transmitting said data to said data collection station,</p> <p>second detector means for detecting in a broadcast transmission at least one instruction, and</p> <p>second processor means operatively connected to said transmission means and said second detector means for causing said transmission means to transmit said additional information in response to said instruction.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 5,233,654, Claim 16
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable</u></p>	<p>16. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising</p> <p>input means for inputting member information,</p> <p>first memory means for storing said input information,</p> <p>detector means for detecting in a broadcast transmission at least one datum,</p> <p>first processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and outputting data that include additional information besides said input information,</p> <p>second memory means for storing said data,</p> <p>transmission means for transmitting said data to said data collection station,</p> <p>second detector means for detecting in a broadcast</p>

<p><u>processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image</u>, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</p> <p>transferring said at least one control signal to said transmitter; and</p> <p>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	<p>transmission at least one instruction, and</p> <p>second processor means operatively connected to said transmission means and said second detector means for causing said transmission means to transmit said additional information in response to said instruction.</p>
---	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 5,233,654, Claim 16
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u></p> <p>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u></p> <p>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</p> <p>transmitting said at least one control signal from sa</p>	<p>16. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising</p> <p>input means for inputting member information,</p> <p>first memory means for storing said input information,</p> <p>detector means for detecting in a broadcast transmission at least one datum,</p> <p>first processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and outputting data that include additional information besides said input information,</p> <p>second memory means for storing said data,</p> <p>transmission means for transmitting said data to said data collection station,</p> <p>second detector means for detecting in a broadcast transmission at least one instruction, and</p> <p>second processor means operatively connected to said transmission means and said second detector means for causing said transmission means to transmit said additional information in response to said instruction.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 5,233,654, Claim 16
<p>84. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</u></p> <ul style="list-style-type: none"> receiving video at a transmitter station; delivering said video to a transmitter; <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and transmitting said video and said first discrete signal to said at least one receiver station. 	<p>16. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising</p> <ul style="list-style-type: none"> input means for inputting member information, first memory means for storing said input information, detector means for detecting in a broadcast transmission at least one datum, first processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and outputting data that include additional information besides said input information, second memory means for storing said data, transmission means for transmitting said data to said data collection station, second detector means for detecting in a broadcast transmission at least one instruction, and second processor means operatively connected to said transmission means and said second detector means for causing said transmission means to transmit said additional information in response to said instruction.

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 5,233,654, Claim 16
<p>93. <u>A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</u></p> <ul style="list-style-type: none"> receiving at least one information transmission at 	<p>16. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising</p> <ul style="list-style-type: none"> input means for inputting member information, first memory means for storing said input

<p>said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal; detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission; passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor; <u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; <u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>information, detector means for detecting in a broadcast transmission at least one datum, first processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and outputting data that include additional information besides said input information, second memory means for storing said data, transmission means for transmitting said data to said data collection station, second detector means for detecting in a broadcast transmission at least one instruction, and second processor means operatively connected to said transmission means and said second detector means for causing said transmission means to transmit said additional information in response to said instruction.</p>
---	--

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 5,233,654, Claim 16
<p>110. <u>A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</u> <u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of</u></p>	<p>16. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising input means for inputting member information, first memory means for storing said input information, detector means for detecting in a broadcast transmission at least one datum, first processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and outputting data that include additional information besides said input information, second memory means for storing said data,</p>

<p><u>said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u> transferring said at least said first discrete signal to at least one transmitter; <u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u> transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>transmission means for transmitting said data to said data collection station, second detector means for detecting in a broadcast transmission at least one instruction, and second processor means operatively connected to said transmission means and said second detector means for causing said transmission means to transmit said additional information in response to said instruction.</p>
---	---

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 5,233,654, Claim 16
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction,</u> said method comprising the steps of: <u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u> receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and</p>	<p>16. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising input means for inputting member information, first memory means for storing said input information, detector means for detecting in a broadcast transmission at least one datum, first processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and outputting data that include additional information besides said input information, second memory means for storing said data, transmission means for transmitting said data to said data collection station, second detector means for detecting in a broadcast transmission at least one instruction, and second processor means operatively connected to said transmission means and said second detector means for causing said transmission means to transmit said additional information in response to said instruction.</p>

<p>said at least one processor instruction; transferring said at least one control signal to said at least one origination transmitter before a specific time; and transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	
---	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 5,233,654, Claim 16
<p>123. <u>A method of delivering a video presentation</u> at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p>transferring said at least one instruct signal to at least one transmitter;</p> <p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image</u></p>	<p>16. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising</p> <p>input means for inputting member information,</p> <p>first memory means for storing said input information,</p> <p>detector means for detecting in a broadcast transmission at least one datum,</p> <p>first processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and outputting data that include additional information besides said input information,</p> <p>second memory means for storing said data,</p> <p>transmission means for transmitting said data to said data collection station,</p> <p>second detector means for detecting in a broadcast transmission at least one instruction, and</p> <p>second processor means operatively connected to said transmission means and said second detector means for causing said transmission means to transmit said additional information in response to said instruction.</p>

<p>and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and</p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	
--	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 5,233,654, Claim 16
<p>142. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>16. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising</p> <p>input means for inputting member information,</p> <p>first memory means for storing said input information,</p> <p>detector means for detecting in a broadcast transmission at least one datum,</p> <p>first processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and outputting data that include additional information besides said input information,</p> <p>second memory means for storing said data,</p> <p>transmission means for transmitting said data to said data collection station,</p> <p>second detector means for detecting in a broadcast transmission at least one instruction, and</p> <p>second processor means operatively connected to said transmission means and said second detector means for causing said transmission means to transmit said additional information in response to said instruction.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 5,233,654, Claim 16
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u></p> <p>receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal;</p> <p>passing said received video image to an output device for delivery to a user;</p> <p>detecting said at least one first discrete signal;</p> <p>passing information contained in said at least one first discrete signal to a processor in response to said step of detecting;</p> <p><u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u></p> <p>responding, at said processor, to <u>processor instructions comprising said organized information,</u> based on said step of organizing;</p> <p>generating a signal based on said processor instructions; and</p> <p>outputting at least a portion of said video presentation based on said generated signal.</p>	<p>16. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising</p> <p>input means for inputting member information,</p> <p>first memory means for storing said input information,</p> <p>detector means for detecting in a broadcast transmission at least one datum,</p> <p>first processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and outputting data that include additional information besides said input information,</p> <p>second memory means for storing said data,</p> <p>transmission means for transmitting said data to said data collection station,</p> <p>second detector means for detecting in a broadcast transmission at least one instruction, and</p> <p>second processor means operatively connected to said transmission means and said second detector means for causing said transmission means to transmit said additional information in response to said instruction.</p>

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 5,233,654, Claim 16
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at</u></p>	<p>16. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising</p> <p>input means for inputting member information,</p> <p>first memory means for storing said input information,</p> <p>detector means for detecting in a broadcast transmission at least one datum,</p> <p>first processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and</p>

<p><u>said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</u></p> <p>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p><u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>outputting data that include additional information besides said input information,</p> <p>second memory means for storing said data,</p> <p>transmission means for transmitting said data to said data collection station,</p> <p>second detector means for detecting in a broadcast transmission at least one instruction, and</p> <p>second processor means operatively connected to said transmission means and said second detector means for causing said transmission means to transmit said additional information in response to said instruction.</p>
---	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 5,233,654, Claim 16
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p> <p>receiving, at said origination transmitter station, one</p>	<p>16. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising</p> <p>input means for inputting member information,</p> <p>first memory means for storing said input information,</p> <p>detector means for detecting in a broadcast transmission at least one datum,</p> <p>first processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and outputting data that include additional information besides said input information,</p> <p>second memory means for storing said data,</p> <p>transmission means for transmitting said data to said data collection station,</p>

or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and transmitting said one or more control signals from said origination transmitter before a specific time.	second detector means for detecting in a broadcast transmission at least one instruction, and second processor means operatively connected to said transmission means and said second detector means for causing said transmission means to transmit said additional information in response to said instruction.
--	--

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 5,233,654, Claim 16
162. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of discrete signals, said method comprising the steps of:</u> receiving a video image at a transmitter station; delivering said video image to a transmitter; <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> transferring said at least said first of said plurality of discrete signals to said transmitter; and transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.	16. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising input means for inputting member information, first memory means for storing said input information, detector means for detecting in a broadcast transmission at least one datum, first processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and outputting data that include additional information besides said input information, second memory means for storing said data, transmission means for transmitting said data to said data collection station, second detector means for detecting in a broadcast transmission at least one instruction, and second processor means operatively connected to said transmission means and said second detector means for causing said transmission means to transmit said additional information in response to said instruction.

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus.

Application Claim 167	U.S. Pat. No. 5,233,654, Claim 16
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u> receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image; passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen; displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen; detecting said at least a first discrete signal of said downloadable code; passing said at least a first discrete signal of said downloadable code to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> wherein said method delivers said video graphic presentation.</p>	<p>16. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising input means for inputting member information, first memory means for storing said input information, detector means for detecting in a broadcast transmission at least one datum, first processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and outputting data that include additional information besides said input information, second memory means for storing said data, transmission means for transmitting said data to said data collection station, second detector means for detecting in a broadcast transmission at least one instruction, and second processor means operatively connected to said transmission means and said second detector means for causing said transmission means to transmit said additional information in response to said instruction.</p>

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 5,233,654, Claim 16
171. <u>A method of delivering a video graphic</u>	16. A receiver station system for processing

presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;

transferring said at least one discrete signal to a transmitter;

receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said at least one discrete signal and said one or more control signals,

wherein said method delivers said video graphic presentation.

information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising

input means for inputting member information,
first memory means for storing said input information,

detector means for detecting in a broadcast transmission at least one datum,

first processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and outputting data that include additional information besides said input information,

second memory means for storing said data,
transmission means for transmitting said data to said data collection station,

second detector means for detecting in a broadcast transmission at least one instruction, and

second processor means operatively connected to said transmission means and said second detector means for causing said transmission means to transmit said additional information in response to said instruction.

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 5,233,654, Claim 16
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u></p> <p style="padding-left: 40px;">receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</p> <p style="padding-left: 40px;"><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p style="padding-left: 40px;">receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</p> <p style="padding-left: 40px;">transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more</p>	<p>16. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising</p> <p style="padding-left: 40px;">input means for inputting member information,</p> <p style="padding-left: 40px;">first memory means for storing said input information,</p> <p style="padding-left: 40px;">detector means for detecting in a broadcast transmission at least one datum,</p> <p style="padding-left: 40px;">first processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and outputting data that include additional information besides said input information,</p> <p style="padding-left: 40px;">second memory means for storing said data,</p> <p style="padding-left: 40px;">transmission means for transmitting said data to said data collection station,</p> <p style="padding-left: 40px;">second detector means for detecting in a broadcast transmission at least one instruction, and</p> <p style="padding-left: 40px;">second processor means operatively connected to said transmission means and said second detector means for causing said transmission means to transmit said additional information in response to said instruction.</p>

control signals from said origination transmitter before a specific time, wherein said method delivers said video graphic presentation.	
--	--

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 5,233,654, Claim 16
<p>177. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>transferring said one or more instruct signals to said transmitter; and</p> <p>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</p> <p>wherein said method delivers said video graphic</p>	<p>16. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising</p> <p>input means for inputting member information,</p> <p>first memory means for storing said input information,</p> <p>detector means for detecting in a broadcast transmission at least one datum,</p> <p>first processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and outputting data that include additional information besides said input information,</p> <p>second memory means for storing said data,</p> <p>transmission means for transmitting said data to said data collection station,</p> <p>second detector means for detecting in a broadcast transmission at least one instruction, and</p> <p>second processor means operatively connected to said transmission means and said second detector means for causing said transmission means to transmit said additional information in response to said instruction.</p>

presentation.	
---------------	--

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 5,233,654, Claim 16
<p>179. <u>A method of outputting a video graphic presentation</u> at a receiver station including:</p> <ul style="list-style-type: none"> receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image; passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen; displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen; detecting said at least a first discrete signal; passing said at least a first discrete signal to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <p>wherein said method delivers said video graphic presentation.</p>	<p>16. A receiver station system for processing information of a member of a broadcast or cablecast program audience and transferring output to at least one remote data collection station comprising</p> <ul style="list-style-type: none"> input means for inputting member information, first memory means for storing said input information, detector means for detecting in a broadcast transmission at least one datum, first processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and outputting data that include additional information besides said input information, second memory means for storing said data, transmission means for transmitting said data to said data collection station, second detector means for detecting in a broadcast transmission at least one instruction, and second processor means operatively connected to said transmission means and said second detector means for causing said transmission means to transmit said additional information in response to said instruction.

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus.

Application Claim 56	U.S. Pat. No. 5,233,654, Claim 21
<p>56. A method for receiving and processing data for use with an interactive video apparatus, <u>said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source</u>, said method comprising the steps of:</p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p>communicating one of said at least said first request and a second request to a remote data source;</p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p>and</p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>21. A method for collecting information about programming use and usage at the receiver station of a potential member of a broadcast or cablecast programming audience, said receiver station including at least one input means for inputting information of the presence, attentiveness or degree of interest of an audience member, one detector means for detecting information of programming, one processor for processing information about programming use and usage, one output means for outputting programming, and one transmission means for transmitting output to a remote station, said receiver station being programmed to transfer information about programming use and usage to a remote station that collects data for use in statistics, consisting of the steps of:</p> <p>programming said receiver station to process information of an audience member,</p> <p>programming said station to identify information of a programming transmission,</p> <p>inputting information of the presence of an audience member,</p> <p>identifying information of a specific programming transmission outputted at said receiver station and</p> <p>transmitting said information of member presence and</p> <p>said in information of a specific transmission to said remote station thereby to cause said remote station to collect information of the presence of an audience member and of the identity of a programming transmission outputted to said member.</p>

Application Claim 75	U.S. Pat. No. 5,233,654, Claim 21
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image,</u></p>	<p>21. A method for collecting information about programming use and usage at the receiver station of a potential member of a broadcast or cablecast programming audience, said receiver station including at least one input means for inputting information of the presence, attentiveness or degree of interest of an audience member, one detector means for detecting information of programming, one processor for processing information about programming use and usage, one output means for outputting programming, and one transmission means for transmitting output to a remote station, said receiver station being programmed to transfer information about programming use and usage to a</p>

<p>said method comprising the steps of:</p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</u></p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</p> <p>transferring said at least one control signal to said transmitter; and</p> <p>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	<p>remote station that collects data for use in statistics, consisting of the steps of:</p> <p>programming said receiver station to process information of an audience member,</p> <p>programming said station to identify information of a programming transmission,</p> <p>inputting information of the presence of an audience member,</p> <p>identifying information of a specific programming transmission outputted at said receiver station and transmitting said information of member presence and</p> <p>said in information of a specific transmission to said remote station thereby to cause said remote station to collect information of the presence of an audience member and of the identity of a programming transmission outputted to said member.</p>
---	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 80	U.S. Pat. No. 5,233,654, Claim 21
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u></p> <p>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u></p> <p>receiving, at said origination transmitter station, at</p>	<p>21. A method for collecting information about programming use and usage at the receiver station of a potential member of a broadcast or cablecast programming audience, said receiver station including at least one input means for inputting information of the presence, attentiveness or degree of interest of an audience member, one detector means for detecting information of programming, one processor for processing information about programming use and usage, one output means for outputting programming, and one transmission means for transmitting output to a remote station, said receiver station being programmed to transfer information about programming use and usage to a remote station that collects data for use in statistics, consisting of the steps of:</p> <p>programming said receiver station to process information of an audience member,</p> <p>programming said station to identify information of</p>

<p>least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</p> <p>transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>a programming transmission,</p> <p>inputting information of the presence of an audience member,</p> <p>identifying information of a specific programming transmission outputted at said receiver station and</p> <p>transmitting said information of member presence and</p> <p>said in information of a specific transmission to said remote station thereby to cause said remote station to collect information of the presence of an audience member and of the identity of a programming transmission outputted to said member.</p>
---	--

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations in an operating environment of a receiver station .

Application Claim 84	U.S. Pat. No. 5,233,654, Claim 21
<p>84. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, <u>wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals</u> and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <p>receiving video at a transmitter station;</p> <p>delivering said video to a transmitter;</p> <p><u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u></p> <p>transferring said first discrete signal to said transmitter; and</p> <p>transmitting said video and said first discrete signal to said at least one receiver station.</p>	<p>21. A method for collecting information about programming use and usage at the receiver station of a potential member of a broadcast or cablecast programming audience, said receiver station including at least one input means for inputting information of the presence, attentiveness or degree of interest of an audience member, one detector means for detecting information of programming, one processor for processing information about programming use and usage, one output means for outputting programming, and one transmission means for transmitting output to a remote station, said receiver station being programmed to transfer information about programming use and usage to a remote station that collects data for use in statistics, consisting of the steps of:</p> <p>programming said receiver station to process information of an audience member,</p> <p>programming said station to identify information of a programming transmission,</p> <p>inputting information of the presence of an audience member,</p> <p>identifying information of a specific programming transmission outputted at said receiver station and</p> <p>transmitting said information of member presence and</p> <p>said in information of a specific transmission to said remote station thereby to cause said remote station to collect information of the presence of an audience member and of the identity of a programming</p>

	transmission outputted to said member.
--	--

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations in an operating environment of a receiver station .

Application Claim 93	U.S. Pat. No. 5,233,654, Claim 21
<p>93. A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <p>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal;</p> <p>detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission;</p> <p>passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor;</p> <p><u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>21. A method for collecting information about programming use and usage at the receiver station of a potential member of a broadcast or cablecast programming audience, said receiver station including at least one input means for inputting information of the presence, attentiveness or degree of interest of an audience member, one detector means for detecting information of programming, one processor for processing information about programming use and usage, one output means for outputting programming, and one transmission means for transmitting output to a remote station, said receiver station being programmed to transfer information about programming use and usage to a remote station that collects data for use in statistics, consisting of the steps of:</p> <p>programming said receiver station to process information of an audience member,</p> <p>programming said station to identify information of a programming transmission,</p> <p>inputting information of the presence of an audience member,</p> <p>identifying information of a specific programming transmission outputted at said receiver station and transmitting said information of member presence and</p> <p>said in information of a specific transmission to said remote station thereby to cause said remote station to collect information of the presence of an audience member and of the identity of a programming transmission outputted to said member.</p>

Application Claim 110	U.S. Pat. No. 5,233,654, Claim 21
<p>110. <u>A method of outputting a video presentation at at least one of a plurality of receiver stations each of</u></p>	<p>21. A method for collecting information about programming use and usage at the receiver station of</p>

<p>which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</p> <p><u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u></p> <p>transferring said at least said first discrete signal to at least one transmitter;</p> <p><u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u></p> <p>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>a potential member of a broadcast or cablecast programming audience, said receiver station including at least one input means for inputting information of the presence, attentiveness or degree of interest of an audience member, one detector means for detecting information of programming, one processor for processing information about programming use and usage, one output means for outputting programming, and one transmission means for transmitting output to a remote station, said receiver station being programmed to transfer information about programming use and usage to a remote station that collects data for use in statistics, consisting of the steps of:</p> <p>programming said receiver station to process information of an audience member,</p> <p>programming said station to identify information of a programming transmission,</p> <p>inputting information of the presence of an audience member,</p> <p>identifying information of a specific programming transmission outputted at said receiver station and transmitting said information of member presence and</p> <p>said in information of a specific transmission to said remote station thereby to cause said remote station to collect information of the presence of an audience member and of the identity of a programming transmission outputted to said member.</p>
---	--

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations in an operating environment of a receiver station .

Application Claim 116	U.S. Pat. No. 5,233,654, Claim 21
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u></p>	<p>21. A method for collecting information about programming use and usage at the receiver station of a potential member of a broadcast or cablecast programming audience, said receiver station including at least one input means for inputting information of the presence, attentiveness or degree of interest of an audience member, one detector means for detecting information of programming, one processor for processing information about programming use and usage, one output means for outputting programming, and one transmission means for transmitting output to a remote station, said</p>

<p><u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u></p> <p>receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</p> <p>transferring said at least one control signal to said at least one origination transmitter before a specific time; and</p> <p>transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	<p>receiver station being programmed to transfer information about programming use and usage to a remote station that collects data for use in statistics, consisting of the steps of:</p> <p style="padding-left: 20px;">programming said receiver station to process information of an audience member,</p> <p style="padding-left: 20px;">programming said station to identify information of a programming transmission,</p> <p style="padding-left: 20px;">inputting information of the presence of an audience member,</p> <p style="padding-left: 20px;">identifying information of a specific programming transmission outputted at said receiver station and transmitting said information of member presence and</p> <p style="padding-left: 20px;">said in information of a specific transmission to said remote station thereby to cause said remote station to collect information of the presence of an audience member and of the identity of a programming transmission outputted to said member.</p>
---	---

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations in an operating environment of a receiver station .

Application Claim 123	U.S. Pat. No. 5,233,654, Claim 21
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u></p> <p style="padding-left: 20px;"><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p style="padding-left: 20px;">transferring said at least one instruct signal to at</p>	<p>21. A method for collecting information about programming use and usage at the receiver station of a potential member of a broadcast or cablecast programming audience, said receiver station including at least one input means for inputting information of the presence, attentiveness or degree of interest of an audience member, one detector means for detecting information of programming, one processor for processing information about programming use and usage, one output means for outputting programming, and one transmission means for transmitting output to a remote station, said receiver station being programmed to transfer information about programming use and usage to a remote station that collects data for use in statistics, consisting of the steps of:</p> <p style="padding-left: 20px;">programming said receiver station to process information of an audience member,</p> <p style="padding-left: 20px;">programming said station to identify information of a programming transmission,</p> <p style="padding-left: 20px;">inputting information of the presence of an</p>

<p>least one transmitter; <u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and</u> transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	<p>audience member, identifying information of a specific programming transmission outputted at said receiver station and transmitting said information of member presence and said in information of a specific transmission to said remote station thereby to cause said remote station to collect information of the presence of an audience member and of the identity of a programming transmission outputted to said member.</p>
---	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations in an operating environment of a receiver station .

Application Claim 142	U.S. Pat. No. 5,233,654, Claim 21
<p>142. A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of: receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal; detecting said at least a first discrete signal and said at least one control signal in said information transmission; passing said detected at least a first discrete signal to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> passing at least one processor instruction from or within said at least one processor, <u>said at least one</u></p>	<p>21. A method for collecting information about programming use and usage at the receiver station of a potential member of a broadcast or cablecast programming audience, said receiver station including at least one input means for inputting information of the presence, attentiveness or degree of interest of an audience member, one detector means for detecting information of programming, one processor for processing information about programming use and usage, one output means for outputting programming, and one transmission means for transmitting output to a remote station, said receiver station being programmed to transfer information about programming use and usage to a remote station that collects data for use in statistics, consisting of the steps of: programming said receiver station to process information of an audience member,</p>

<p><u>processor instruction comprising said organized information from said step of organizing;</u> responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; <u>generating only a portion of said video image based on said step of responding to said at least one processor instruction;</u> and <u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>programming said station to identify information of a programming transmission, inputting information of the presence of an audience member, identifying information of a specific programming transmission outputted at said receiver station and transmitting said information of member presence and said in information of a specific transmission to said remote station thereby to cause said remote station to collect information of the presence of an audience member and of the identity of a programming transmission outputted to said member.</p>
--	--

Application Claim 143	U.S. Pat. No. 5,233,654, Claim 21
<p>143. A method of outputting a video presentation at a receiver station including: receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal; responding, at said processor, to processor instructions comprising said organized information, based on said step of organizing; generating a signal based on said processor instructions; and outputting at least a portion of said video presentation based on said generated signal.</p>	<p>21. A method for collecting information about programming use and usage at the receiver station of a potential member of a broadcast or cablecast programming audience, said receiver station including at least one input means for inputting information of the presence, attentiveness or degree of interest of an audience member, one detector means for detecting information of programming, one processor for processing information about programming use and usage, one output means for outputting programming, and one transmission means for transmitting output to a remote station, said receiver station being programmed to transfer information about programming use and usage to a remote station that collects data for use in statistics, consisting of the steps of: programming said receiver station to process information of an audience member, programming said station to identify information of a programming transmission, inputting information of the presence of an audience member, identifying information of a specific programming transmission outputted at said receiver station and transmitting said information of member presence and said in information of a specific transmission to said remote station thereby to cause said remote station to collect information of the presence of an audience member and of the identity of a programming transmission outputted to said member.</p>

Application Claim 152	U.S. Pat. No. 5,233,654, Claim 21
<p>152. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process <u>downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation</u> and have a target processor to process data, <u>said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station</u>, said method comprising the steps of:</p> <p>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and <u>wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image</u>;</p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>21. A method for collecting information about programming use and usage at the receiver station of a potential member of a broadcast or cablecast programming audience, said receiver station including at least one input means for inputting information of the presence, attentiveness or degree of interest of an audience member, one detector means for detecting information of programming, one processor for processing information about programming use and usage, one output means for outputting programming, and one transmission means for transmitting output to a remote station, said receiver station being programmed to transfer information about programming use and usage to a remote station that collects data for use in statistics, consisting of the steps of:</p> <p>programming said receiver station to process information of an audience member,</p> <p>programming said station to identify information of a programming transmission,</p> <p>inputting information of the presence of an audience member,</p> <p>identifying information of a specific programming transmission outputted at said receiver station and transmitting said information of member presence and</p> <p>said in information of a specific transmission to said remote station thereby to cause said remote station to collect information of the presence of an audience member and of the identity of a programming transmission outputted to said member.</p>

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations in an operating environment of a receiver station .

Application Claim 157	U.S. Pat. No. 5,233,654, Claim 21
157. <u>A method of delivering a video presentation</u>	21. A method for collecting information about

<p>at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</p> <p>transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>programming use and usage at the receiver station of a potential member of a broadcast or cablecast programming audience, said receiver station including at least one input means for inputting information of the presence, attentiveness or degree of interest of an audience member, one detector means for detecting information of programming, one processor for processing information about programming use and usage, one output means for outputting programming, and one transmission means for transmitting output to a remote station, said receiver station being programmed to transfer information about programming use and usage to a remote station that collects data for use in statistics, consisting of the steps of:</p> <p>programming said receiver station to process information of an audience member,</p> <p>programming said station to identify information of a programming transmission,</p> <p>inputting information of the presence of an audience member,</p> <p>identifying information of a specific programming transmission outputted at said receiver station and transmitting said information of member presence and</p> <p>said in information of a specific transmission to said remote station thereby to cause said remote station to collect information of the presence of an audience member and of the identity of a programming transmission outputted to said member.</p>
---	---

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations in an operating environment of a receiver station .

Application Claim 162	U.S. Pat. No. 5,233,654, Claim 21
<p>162. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals,</u> said method comprising the steps of:</p> <p>receiving a video image at a transmitter station;</p> <p>delivering said video image to a transmitter;</p> <p><u>receiving said at least said first of said plurality of</u></p>	<p>21. A method for collecting information about programming use and usage at the receiver station of a potential member of a broadcast or cablecast programming audience, said receiver station including at least one input means for inputting information of the presence, attentiveness or degree of interest of an audience member, one detector means for detecting information of programming, one processor for processing information about programming use and usage, one output means for outputting programming, and one transmission means for transmitting output to a remote station, said</p>

<p><u>discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> transferring said at least said first of said plurality of discrete signals to said transmitter; and transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>receiver station being programmed to transfer information about programming use and usage to a remote station that collects data for use in statistics, consisting of the steps of: programming said receiver station to process information of an audience member, programming said station to identify information of a programming transmission, inputting information of the presence of an audience member, identifying information of a specific programming transmission outputted at said receiver station and transmitting said information of member presence and said in information of a specific transmission to said remote station thereby to cause said remote station to collect information of the presence of an audience member and of the identity of a programming transmission outputted to said member.</p>
--	---

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations in an operating environment of a receiver station .

Application Claim 167	U.S. Pat. No. 5,233,654, Claim 21
<p>167. A method of outputting a video graphic presentation at a receiver station including: receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image; passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen; displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen; detecting said at least a first discrete signal of said downloadable code; passing said at least a first discrete signal of said downloadable code to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p>	<p>21. A method for collecting information about programming use and usage at the receiver station of a potential member of a broadcast or cablecast programming audience, said receiver station including at least one input means for inputting information of the presence, attentiveness or degree of interest of an audience member, one detector means for detecting information of programming, one processor for processing information about programming use and usage, one output means for outputting programming, and one transmission means for transmitting output to a remote station, said receiver station being programmed to transfer information about programming use and usage to a remote station that collects data for use in statistics, consisting of the steps of: programming said receiver station to process information of an audience member, programming said station to identify information of a programming transmission, inputting information of the presence of an audience member, identifying information of a specific programming</p>

<p>responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u></p> <p><u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u></p> <p>wherein said method delivers said video graphic presentation.</p>	<p>transmission outputted at said receiver station and transmitting said information of member presence and</p> <p>said in information of a specific transmission to said remote station thereby to cause said remote station to collect information of the presence of an audience member and of the identity of a programming transmission outputted to said member.</p>
--	--

Application Claim 171	U.S. Pat. No. 5,233,654, Claim 21
<p>171. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to <u>pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image,</u> said method comprising the steps of:</p> <p><u>receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</u></p>	<p>21. A method for collecting information about programming use and usage at the receiver station of a potential member of a broadcast or cablecast programming audience, said receiver station including at least one input means for inputting information of the presence, attentiveness or degree of interest of an audience member, one detector means for detecting information of programming, one processor for processing information about programming use and usage, one output means for outputting programming, and one transmission means for transmitting output to a remote station, said receiver station being programmed to transfer information about programming use and usage to a remote station that collects data for use in statistics, consisting of the steps of:</p> <p>programming said receiver station to process information of an audience member,</p> <p>programming said station to identify information of a programming transmission,</p> <p>inputting information of the presence of an audience member,</p> <p>identifying information of a specific programming transmission outputted at said receiver station and transmitting said information of member presence and</p> <p>said in information of a specific transmission to said remote station thereby to cause said remote station to collect information of the presence of an audience</p>

<p>transferring said at least one discrete signal to a transmitter;</p> <p><u>receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said at least one discrete signal and said one or more control signals,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>member and of the identity of a programming transmission outputted to said member.</p>
--	---

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations in an operating environment of a receiver station .

Application Claim 175	U.S. Pat. No. 5,233,654, Claim 21
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u></p> <p>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor</u></p>	<p>21. A method for collecting information about programming use and usage at the receiver station of a potential member of a broadcast or cablecast programming audience, said receiver station including at least one input means for inputting information of the presence, attentiveness or degree of interest of an audience member, one detector means for detecting information of programming, one processor for processing information about programming use and usage, one output means for outputting programming, and one transmission means for transmitting output to a remote station, said receiver station being programmed to transfer information about programming use and usage to a remote station that collects data for use in statistics, consisting of the steps of:</p> <p>programming said receiver station to process information of an audience member,</p> <p>programming said station to identify information of</p>

<p><u>instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</p> <p>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>a programming transmission,</p> <p>inputting information of the presence of an audience member,</p> <p>identifying information of a specific programming transmission outputted at said receiver station and transmitting said information of member presence and</p> <p>said in information of a specific transmission to said remote station thereby to cause said remote station to collect information of the presence of an audience member and of the identity of a programming transmission outputted to said member.</p>
--	---

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations in an operating environment of a receiver station .

Application Claim 177	U.S. Pat. No. 5,233,654, Claim 21
<p>177. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p>	<p>21. A method for collecting information about programming use and usage at the receiver station of a potential member of a broadcast or cablecast programming audience, said receiver station including at least one input means for inputting information of the presence, attentiveness or degree of interest of an audience member, one detector means for detecting information of programming, one processor for processing information about programming use and usage, one output means for outputting programming, and one transmission means for transmitting output to a remote station, said receiver station being programmed to transfer information about programming use and usage to a remote station that collects data for use in statistics,</p>

<p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>transferring said one or more instruct signals to said transmitter; and</p> <p>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>consisting of the steps of:</p> <p>programming said receiver station to process information of an audience member,</p> <p>programming said station to identify information of a programming transmission,</p> <p>inputting information of the presence of an audience member,</p> <p>identifying information of a specific programming transmission outputted at said receiver station and transmitting said information of member presence and</p> <p>said in information of a specific transmission to said remote station thereby to cause said remote station to collect information of the presence of an audience member and of the identity of a programming transmission outputted to said member.</p>
---	---

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations in an operating environment of a receiver station .

Application Claim 179	U.S. Pat. No. 5,233,654, Claim 21
<p>179. A method of outputting a video graphic presentation at a receiver station including:</p> <p>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</p> <p>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal;</p> <p>passing said at least a first discrete signal to at least one processor;</p>	<p>21. A method for collecting information about programming use and usage at the receiver station of a potential member of a broadcast or cablecast programming audience, said receiver station including at least one input means for inputting information of the presence, attentiveness or degree of interest of an audience member, one detector means for detecting information of programming, one processor for processing information about programming use and usage, one output means for outputting programming, and one transmission means for transmitting output to a remote station, said receiver station being programmed to transfer information about programming use and usage to a remote station that collects data for use in statistics, consisting of the steps of:</p> <p>programming said receiver station to process</p>

<p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u></p> <p><u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u></p> <p>wherein said method delivers said video graphic presentation.</p>	<p>information of an audience member,</p> <p>programming said station to identify information of a programming transmission,</p> <p>inputting information of the presence of an audience member,</p> <p>identifying information of a specific programming transmission outputted at said receiver station and transmitting said information of member presence and</p> <p>said in information of a specific transmission to said remote station thereby to cause said remote station to collect information of the presence of an audience member and of the identity of a programming transmission outputted to said member.</p>
--	---

Application Claim 56	U.S. Pat. No. 5,233,654, Claim 32
<p>56. A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying <u>a video presentation comprising a locally generated image and an image received from a remote video source</u>, said method comprising the steps of:</p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p>and</p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>32. A method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station, with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to a detected instruct-to-respond signal, consisting of the steps of:</p> <p>programming at least some of said last named audience stations to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission,</p> <p>programming at least one of said some to process information it holds in response to an instruct-to-respond signal,</p> <p>transmitting mass medium programming that elicits audience reactions,</p> <p>receiving said transmission at a plurality of said audience stations and outputting the corresponding mass medium programming,</p> <p>transmitting to said plurality of audience stations an instruct-to-respond signal,</p> <p>inputting information of the reaction of an audience member at a selected audience station that is outputting said mass medium programming and is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission,</p> <p>detecting the presence of said instruct-to-respond signal at said selected audience station and combining information of said signal to at least one processor of said station,</p> <p>causing said station to process its reaction information in response to said instruct-to-respond signal and output data that include response</p>

	information other than said reaction information, and receiving at least a portion of the output of said processor at said data collection station, thereby to cause said data collection station to collect at least a portion of said response information.

Application Claim 75	U.S. Pat. No. 5,233,654, Claim 32
<p>75. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, <u>said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image</u>, said method comprising the steps of:</p> <p>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</p> <p>transferring said at least one control signal to said transmitter; and</p> <p>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	<p>32. A method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station, with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to a detected instruct-to-respond signal, consisting of the steps of:</p> <p>programming at least some of said last named audience stations to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission,</p> <p>programming at least one of said some to process information it holds in response to an instruct-to-respond signal,</p> <p>transmitting mass medium programming that elicits audience reactions,</p> <p>receiving said transmission at a plurality of said audience stations and outputting the corresponding mass medium programming,</p> <p>transmitting to said plurality of audience stations an instruct-to-respond signal,</p> <p>inputting information of the reaction of an audience member at a selected audience station that is outputting said mass medium programming and is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission,</p> <p>detecting the presence of said instruct-to-respond signal at said selected audience station and combining information of said signal to at least one processor of said station,</p> <p>causing said station to process its reaction information in response to said instruct-to-respond signal and output data that include response</p>

	information other than said reaction information, and receiving at least a portion of the output of said processor at said data collection station, thereby to cause said data collection station to collect at least a portion of said response information.

Application Claim 80	U.S. Pat. No. 5,233,654, Claim 32
<p>80. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u></p> <p>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</p> <p>transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>32. A method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station, with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to a detected instruct-to-respond signal, consisting of the steps of:</p> <p>programming at least some of said last named audience stations to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission,</p> <p>programming at least one of said some to process information it holds in response to an instruct-to-respond signal,</p> <p>transmitting mass medium programming that elicits audience reactions,</p> <p>receiving said transmission at a plurality of said audience stations and outputting the corresponding mass medium programming,</p> <p>transmitting to said plurality of audience stations an instruct-to-respond signal,</p> <p>inputting information of the reaction of an audience member at a selected audience station that is outputting said mass medium programming and is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission,</p> <p>detecting the presence of said instruct-to-respond signal at said selected audience station and combining information of said signal to at least one processor of said station,</p> <p>causing said station to process its reaction information in response to said instruct-to-respond signal and output data that include response</p>

	information other than said reaction information, and receiving at least a portion of the output of said processor at said data collection station, thereby to cause said data collection station to collect at least a portion of said response information.

Application Claim 84	U.S. Pat. No. 5,233,654, Claim 32
<p>84. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, <u>wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals</u> and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <p style="padding-left: 40px;">receiving video at a transmitter station;</p> <p style="padding-left: 40px;">delivering said video to a transmitter;</p> <p style="padding-left: 40px;"><u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u></p> <p style="padding-left: 40px;">transferring said first discrete signal to said transmitter; and</p> <p style="padding-left: 40px;">transmitting said video and said first discrete signal to said at least one receiver station.</p>	<p>32. A method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station, with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to a detected instruct-to-respond signal, consisting of the steps of:</p> <p style="padding-left: 40px;">programming at least some of said last named audience stations to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission,</p> <p style="padding-left: 40px;">programming at least one of said some to process information it holds in response to an instruct-to-respond signal,</p> <p style="padding-left: 40px;">transmitting mass medium programming that elicits audience reactions,</p> <p style="padding-left: 40px;">receiving said transmission at a plurality of said audience stations and outputting the corresponding mass medium programming,</p> <p style="padding-left: 40px;">transmitting to said plurality of audience stations an instruct-to-respond signal,</p> <p style="padding-left: 40px;">inputting information of the reaction of an audience member at a selected audience station that is outputting said mass medium programming and is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission,</p> <p style="padding-left: 40px;">detecting the presence of said instruct-to-respond signal at said selected audience station and combining information of said signal to at least one processor of said station,</p> <p style="padding-left: 40px;">causing said station to process its reaction information in response to said instruct-to-respond signal and output data that include response</p>

	information other than said reaction information, and receiving at least a portion of the output of said processor at said data collection station, thereby to cause said data collection station to collect at least a portion of said response information.

Application Claim 93	U.S. Pat. No. 5,233,654, Claim 32
<p>93. A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <p>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal;</p> <p>detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission;</p> <p>passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor;</p> <p><u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;</p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>32. A method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station, with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to a detected instruct-to-respond signal, consisting of the steps of:</p> <p>programming at least some of said last named audience stations to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission,</p> <p>programming at least one of said some to process information it holds in response to an instruct-to-respond signal,</p> <p>transmitting mass medium programming that elicits audience reactions,</p> <p>receiving said transmission at a plurality of said audience stations and outputting the corresponding mass medium programming,</p> <p>transmitting to said plurality of audience stations an instruct-to-respond signal,</p> <p>inputting information of the reaction of an audience member at a selected audience station that is outputting said mass medium programming and is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission,</p> <p>detecting the presence of said instruct-to-respond signal at said selected audience station and combining information of said signal to at least one processor of said station,</p> <p>causing said station to process its reaction information in response to said instruct-to-respond signal and output data that include response</p>

	information other than said reaction information, and receiving at least a portion of the output of said processor at said data collection station, thereby to cause said data collection station to collect at least a portion of said response information.

Application Claim 110	U.S. Pat. No. 5,233,654, Claim 32
<p>110. A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</p> <p><u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u></p> <p>transferring said at least said first discrete signal to at least one transmitter;</p> <p><u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u></p> <p>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>32. A method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station, with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to a detected instruct-to-respond signal, consisting of the steps of:</p> <p>programming at least some of said last named audience stations to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission,</p> <p>programming at least one of said some to process information it holds in response to an instruct-to-respond signal,</p> <p>transmitting mass medium programming that elicits audience reactions,</p> <p>receiving said transmission at a plurality of said audience stations and outputting the corresponding mass medium programming,</p> <p>transmitting to said plurality of audience stations an instruct-to-respond signal,</p> <p>inputting information of the reaction of an audience member at a selected audience station that is outputting said mass medium programming and is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission,</p> <p>detecting the presence of said instruct-to-respond signal at said selected audience station and combining information of said signal to at least one processor of said station,</p> <p>causing said station to process its reaction information in response to said instruct-to-respond signal and output data that include response</p>

	information other than said reaction information, and receiving at least a portion of the output of said processor at said data collection station, thereby to cause said data collection station to collect at least a portion of said response information.

Application Claim 116	U.S. Pat. No. 5,233,654, Claim 32
<p>116. A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, <u>wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction</u>, said method comprising the steps of:</p> <p><u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u></p> <p>receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</p> <p>transferring said at least one control signal to said at least one origination transmitter before a specific time; and</p> <p>transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	<p>32. A method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station, with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to a detected instruct-to-respond signal, consisting of the steps of:</p> <p>programming at least some of said last named audience stations to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission,</p> <p>programming at least one of said some to process information it holds in response to an instruct-to-respond signal,</p> <p>transmitting mass medium programming that elicits audience reactions,</p> <p>receiving said transmission at a plurality of said audience stations and outputting the corresponding mass medium programming,</p> <p>transmitting to said plurality of audience stations an instruct-to-respond signal,</p> <p>inputting information of the reaction of an audience member at a selected audience station that is outputting said mass medium programming and is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission,</p> <p>detecting the presence of said instruct-to-respond signal at said selected audience station and combining information of said signal to at least one processor of said station,</p> <p>causing said station to process its reaction information in response to said instruct-to-respond signal and output data that include response</p>

	information other than said reaction information, and receiving at least a portion of the output of said processor at said data collection station, thereby to cause said data collection station to collect at least a portion of said response information.

Application Claim 123	U.S. Pat. No. 5,233,654, Claim 32
<p>123. A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p>transferring said at least one instruct signal to at least one transmitter;</p> <p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and</u></p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	<p>32. A method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station, with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to a detected instruct-to-respond signal, consisting of the steps of:</p> <p>programming at least some of said last named audience stations to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission,</p> <p>programming at least one of said some to process information it holds in response to an instruct-to-respond signal,</p> <p>transmitting mass medium programming that elicits audience reactions,</p> <p>receiving said transmission at a plurality of said audience stations and outputting the corresponding mass medium programming,</p> <p>transmitting to said plurality of audience stations an instruct-to-respond signal,</p> <p>inputting information of the reaction of an audience member at a selected audience station that is outputting said mass medium programming and is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission,</p> <p>detecting the presence of said instruct-to-respond signal at said selected audience station and combining information of said signal to at least one processor of said station,</p> <p>causing said station to process its reaction information in response to said instruct-to-respond signal and output data that include response</p>

	information other than said reaction information, and receiving at least a portion of the output of said processor at said data collection station, thereby to cause said data collection station to collect at least a portion of said response information.

Application Claim 142	U.S. Pat. No. 5,233,654, Claim 32
<p>142. A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;</p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>32. A method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station, with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to a detected instruct-to-respond signal, consisting of the steps of:</p> <p>programming at least some of said last named audience stations to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission,</p> <p>programming at least one of said some to process information it holds in response to an instruct-to-respond signal,</p> <p>transmitting mass medium programming that elicits audience reactions,</p> <p>receiving said transmission at a plurality of said audience stations and outputting the corresponding mass medium programming,</p> <p>transmitting to said plurality of audience stations an instruct-to-respond signal,</p> <p>inputting information of the reaction of an audience member at a selected audience station that is outputting said mass medium programming and is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission,</p> <p>detecting the presence of said instruct-to-respond signal at said selected audience station and combining information of said signal to at least one processor of said station,</p> <p>causing said station to process its reaction information in response to said instruct-to-respond signal and output data that include response</p>

	information other than said reaction information, and receiving at least a portion of the output of said processor at said data collection station, thereby to cause said data collection station to collect at least a portion of said response information.
--	---

This Page Blank (uspto)

Application Claim 143	U.S. Pat. No. 5,233,654, Claim 32
<p>143. A method of outputting a video presentation at a receiver station including:</p> <ul style="list-style-type: none"> receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to processor instructions comprising said organized information, based on said step of organizing; generating a signal based on said processor instructions; and <u>outputting at least a portion of said video presentation based on said generated signal.</u> 	<p>32. A method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station, with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to a detected instruct-to-respond signal, consisting of the steps of:</p> <ul style="list-style-type: none"> programming at least some of said last named audience stations to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, programming at least one of said some to process information it holds in response to an instruct-to-respond signal, transmitting mass medium programming that elicits audience reactions, receiving said transmission at a plurality of said audience stations and outputting the corresponding mass medium programming, transmitting to said plurality of audience stations an instruct-to-respond signal, inputting information of the reaction of an audience member at a selected audience station that is outputting said mass medium programming and is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, detecting the presence of said instruct-to-respond signal at said selected audience station and combining information of said signal to at least one processor of said station, causing said station to process its reaction information in response to said instruct-to-respond signal and output data that include response

	information other than said reaction information, and receiving at least a portion of the output of said processor at said data collection station, thereby to cause said data collection station to collect at least a portion of said response information.

Application Claim 152	U.S. Pat. No. 5,233,654, Claim 32
<p>152. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process <u>downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation</u> and have a target processor to process data, <u>said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station</u>, said method comprising the steps of:</p> <p>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p><u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>32. A method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station, with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to a detected instruct-to-respond signal, consisting of the steps of:</p> <p>programming at least some of said last named audience stations to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission,</p> <p>programming at least one of said some to process information it holds in response to an instruct-to-respond signal,</p> <p>transmitting mass medium programming that elicits audience reactions,</p> <p>receiving said transmission at a plurality of said audience stations and outputting the corresponding mass medium programming,</p> <p>transmitting to said plurality of audience stations an instruct-to-respond signal,</p> <p>inputting information of the reaction of an audience member at a selected audience station that is outputting said mass medium programming and is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission,</p> <p>detecting the presence of said instruct-to-respond signal at said selected audience station and combining information of said signal to at least one processor of said station,</p> <p>causing said station to process its reaction information in response to said instruct-to-respond signal and output data that include response</p>

	information other than said reaction information, and receiving at least a portion of the output of said processor at said data collection station, thereby to cause said data collection station to collect at least a portion of said response information.

Application Claim 157	U.S. Pat. No. 5,233,654, Claim 32
<p>157. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</p> <p>transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>32. A method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station, with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to a detected instruct-to-respond signal, consisting of the steps of:</p> <p>programming at least some of said last named audience stations to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission,</p> <p>programming at least one of said some to process information it holds in response to an instruct-to-respond signal,</p> <p>transmitting mass medium programming that elicits audience reactions,</p> <p>receiving said transmission at a plurality of said audience stations and outputting the corresponding mass medium programming,</p> <p>transmitting to said plurality of audience stations an instruct-to-respond signal,</p> <p>inputting information of the reaction of an audience member at a selected audience station that is outputting said mass medium programming and is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission,</p> <p>detecting the presence of said instruct-to-respond signal at said selected audience station and combining information of said signal to at least one processor of said station,</p> <p>causing said station to process its reaction information in response to said instruct-to-respond signal and output data that include response</p>

	information other than said reaction information, and receiving at least a portion of the output of said processor at said data collection station, thereby to cause said data collection station to collect at least a portion of said response information.

Application Claim 162	U.S. Pat. No. 5,233,654, Claim 32
<p>162. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals</u>, said method comprising the steps of:</p> <p style="padding-left: 40px;">receiving a video image at a transmitter station; delivering said video image to a transmitter; <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u></p> <p style="padding-left: 40px;">transferring said at least said first of said plurality of discrete signals to said transmitter; and</p> <p style="padding-left: 40px;">transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>32. A method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station, with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to a detected instruct-to-respond signal, consisting of the steps of:</p> <p style="padding-left: 40px;">programming at least some of said last named audience stations to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission,</p> <p style="padding-left: 40px;">programming at least one of said some to process information it holds in response to an instruct-to-respond signal,</p> <p style="padding-left: 40px;">transmitting mass medium programming that elicits audience reactions,</p> <p style="padding-left: 40px;">receiving said transmission at a plurality of said audience stations and outputting the corresponding mass medium programming,</p> <p style="padding-left: 40px;">transmitting to said plurality of audience stations an instruct-to-respond signal,</p> <p style="padding-left: 40px;">inputting information of the reaction of an audience member at a selected audience station that is outputting said mass medium programming and is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission,</p> <p style="padding-left: 40px;">detecting the presence of said instruct-to-respond signal at said selected audience station and combining information of said signal to at least one processor of said station,</p> <p style="padding-left: 40px;">causing said station to process its reaction information in response to said instruct-to-respond signal and output data that include response</p>

	information other than said reaction information, and receiving at least a portion of the output of said processor at said data collection station, thereby to cause said data collection station to collect at least a portion of said response information.

Application Claim 56	U.S. Pat. No. 5,233,654, Claim 33
<p>56. A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</p> <ul style="list-style-type: none"> originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation; communicating one of said at least said first request and a second request to a remote data source; receiving from said remote data source said data to serve as a basis for displaying said video presentation; processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source; and displaying said locally generated image at said video output device in conjunction with said image from said remote video source. 	<p>33. In a method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to a detected instruct-to-respond signal; and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, at least one of said some is programmed to process information it holds in response to an instruct-to-respond signal, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said transmission and output the corresponding mass medium programming, and information of the reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, the step of:</p> <ul style="list-style-type: none"> transmitting to said plurality of audience stations an instruct-to-respond signal, thereby causing said selected audience station to detect the presence of said instruct-to-respond signal, combine information of said signal to at least one processor of said station, process its reaction information in response to said instruct-to-respond signal and output data that include response information other than said reaction information, said data collection station to receive at least a portion of the output of said processor, and said data collection station to collect at least a portion of said response information.

Application Claim 75	U.S. Pat. No. 5,233,654, Claim 33
<p>75. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</p> <p>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</p> <p>transferring said at least one control signal to said transmitter; and</p> <p>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	<p>33. In a method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to a detected instruct-to-respond signal; and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, at least one of said some is programmed to process information it holds in response to an instruct-to-respond signal, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said transmission and output the corresponding mass medium programming, and information of the reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, the step of:</p> <p>transmitting to said plurality of audience stations an instruct-to-respond signal, thereby causing said selected audience station to detect the presence of said instruct-to-respond signal, combine information of said signal to at least one processor of said station, process its reaction information in response to said instruct-to-respond signal and output data that include response information other than said reaction information, said data collection station to receive at</p>

	least a portion of the output of said processor, and said data collection station to collect at least a portion of said response information.
--	---

Application Claim 80	U.S. Pat. No. 5,233,654, Claim 33
<p>80. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</p> <p style="padding-left: 20px;">receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</p> <p style="padding-left: 20px;">delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</p> <p style="padding-left: 20px;">receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</p> <p style="padding-left: 20px;">transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>33. In a method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to a detected instruct-to-respond signal; and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, at least one of said some is programmed to process information it holds in response to an instruct-to-respond signal, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said transmission and output the corresponding mass medium programming, and information of the reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, the step of:</p> <p style="padding-left: 20px;">transmitting to said plurality of audience stations an instruct-to-respond signal, thereby causing said selected audience station to detect the presence of said instruct-to-respond signal, combine information of said signal to at least one processor of said station, process its reaction information in response to said</p>

	<p>instruct-to-respond signal and output data that include response information other than said reaction information, said data collection station to receive at least a portion of the output of said processor, and said data collection station to collect at least a portion of said response information.</p>
--	--

Application Claim 84	U.S. Pat. No. 5,233,654, Claim 33
<p>84. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving video at a transmitter station; delivering said video to a transmitter; receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video; transferring said first discrete signal to said transmitter; and transmitting said video and said first discrete signal to said at least one receiver station. 	<p>33. In a method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to a detected instruct-to-respond signal; and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, at least one of said some is programmed to process information it holds in response to an instruct-to-respond signal, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said transmission and output the corresponding mass medium programming, and information of the reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, the step of:</p> <ul style="list-style-type: none"> transmitting to said plurality of audience stations an instruct-to-respond signal, thereby causing said selected audience station to detect the presence of said

	<p>instruct-to-respond signal, combine information of said signal to at least one processor of said station, process its reaction information in response to said instruct-to-respond signal and output data that include response information other than said reaction information, said data collection station to receive at least a portion of the output of said processor, and said data collection station to collect at least a portion of said response information.</p>
--	---

Application Claim 93	U.S. Pat. No. 5,233,654, Claim 33
<p>93. A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <p style="padding-left: 20px;">receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal;</p> <p style="padding-left: 20px;">detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission;</p> <p style="padding-left: 20px;">passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor;</p> <p style="padding-left: 20px;">organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</p> <p style="padding-left: 20px;">passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;</p> <p style="padding-left: 20px;">responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p style="padding-left: 20px;">generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</p> <p style="padding-left: 20px;">outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</p>	<p>33. In a method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to a detected instruct-to-respond signal; and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, at least one of said some is programmed to process information it holds in response to an instruct-to-respond signal, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said transmission and output the corresponding mass medium programming, and information of the reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, the step of:</p>

	<p>transmitting to said plurality of audience stations an instruct-to-respond signal, thereby causing said selected audience station to detect the presence of said instruct-to-respond signal, combine information of said signal to at least one processor of said station, process its reaction information in response to said instruct-to-respond signal and output data that include response information other than said reaction information, said data collection station to receive at least a portion of the output of said processor, and said data collection station to collect at least a portion of said response information.</p>
--	--

Application Claim 110	U.S. Pat. No. 5,233,654, Claim 33
<p>110. A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</p> <p style="padding-left: 20px;">receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</p> <p style="padding-left: 20px;">transferring said at least said first discrete signal to at least one transmitter;</p> <p style="padding-left: 20px;">receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</p> <p style="padding-left: 20px;">transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>33. In a method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to a detected instruct-to-respond signal; and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, at least one of said some is programmed to process information it holds in response to an instruct-to-respond signal, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said transmission and output the corresponding mass medium programming, and information of the reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in</p>

	<p>selected fashions to instruction signals associated with a mass medium programming transmission, the step of:</p> <p>transmitting to said plurality of audience stations an instruct-to-respond signal, thereby causing said selected audience station to detect the presence of said instruct-to-respond signal, combine information of said signal to at least one processor of said station, process its reaction information in response to said instruct-to-respond signal and output data that include response information other than said reaction information, said data collection station to receive at least a portion of the output of said processor, and said data collection station to collect at least a portion of said response information.</p>
--	---

Application Claim 116	U.S. Pat. No. 5,233,654, Claim 33
<p>116. A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</p> <p>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</p> <p>receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</p> <p>transferring said at least one control signal to said at least one origination transmitter before a specific time; and</p> <p>transmitting from said at least origination transmitter said first discrete signal and said at least</p>	<p>33. In a method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to a detected instruct-to-respond signal; and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, at least one of said some is programmed to process information it holds in response to an instruct-to-respond signal, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said transmission and output the corresponding mass medium programming, and information of the</p>

one control signal.	<p>reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, the step of:</p> <p>transmitting to said plurality of audience stations an instruct-to-respond signal, thereby causing said selected audience station to detect the presence of said instruct-to-respond signal, combine information of said signal to at least one processor of said station, process its reaction information in response to said instruct-to-respond signal and output data that include response information other than said reaction information, said data collection station to receive at least a portion of the output of said processor, and said data collection station to collect at least a portion of said response information.</p>
---------------------	--

Application Claim 123	U.S. Pat. No. 5,233,654, Claim 33
<p>123. A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</p> <p>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</p> <p>transferring said at least one instruct signal to at least one transmitter;</p> <p>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an</p>	<p>33. In a method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to a detected instruct-to-respond signal; and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, at least one of said some is programmed to process information it holds in response to an instruct-to-respond signal, a transmission station transmits mass medium programming that elicits audience reactions, a</p>

<p>identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and</p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	<p>plurality of said audience stations receive said transmission and output the corresponding mass medium programming, and information of the reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, the step of:</p> <p>transmitting to said plurality of audience stations an instruct-to-respond signal, thereby causing said selected audience station to detect the presence of said instruct-to-respond signal, combine information of said signal to at least one processor of said station, process its reaction information in response to said instruct-to-respond signal and output data that include response information other than said reaction information, said data collection station to receive at least a portion of the output of said processor, and said data collection station to collect at least a portion of said response information.</p>
--	---

Application Claim 142	U.S. Pat. No. 5,233,654, Claim 33
<p>142. A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</p> <p>passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;</p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</p>	<p>33. In a method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to a detected instruct-to-respond signal; and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, at least one of said some is programmed to process information it holds in</p>

<p>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</p>	<p>response to an instruct-to-respond signal, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said transmission and output the corresponding mass medium programming, and information of the reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, the step of:</p> <p>transmitting to said plurality of audience stations an instruct-to-respond signal, thereby causing said selected audience station to detect the presence of said instruct-to-respond signal, combine information of said signal to at least one processor of said station, process its reaction information in response to said instruct-to-respond signal and output data that include response information other than said reaction information, said data collection station to receive at least a portion of the output of said processor, and said data collection station to collect at least a portion of said response information.</p>
---	--

Application Claim 143	U.S. Pat. No. 5,233,654, Claim 33
<p>143. A method of outputting a video presentation at a receiver station including:</p> <p>receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal;</p> <p>passing said received video image to an output device for delivery to a user;</p> <p>detecting said at least one first discrete signal;</p> <p>passing information contained in said at least one first discrete signal to a processor in response to said step of detecting;</p> <p>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</p> <p>responding, at said processor, to processor instructions comprising said organized information, based on said step of organizing;</p> <p>generating a signal based on said processor instructions; and</p> <p>outputting at least a portion of said video presentation based on said generated signal.</p>	<p>33. In a method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to a detected instruct-to-respond signal; and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions</p>

	<p>to instruction signals associated with a mass medium programming transmission, at least one of said some is programmed to process information it holds in response to an instruct-to-respond signal, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said transmission and output the corresponding mass medium programming, and information of the reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, the step of:</p> <p>transmitting to said plurality of audience stations an instruct-to-respond signal, thereby causing said selected audience station to detect the presence of said instruct-to-respond signal, combine information of said signal to at least one processor of said station, process its reaction information in response to said instruct-to-respond signal and output data that include response information other than said reaction information, said data collection station to receive at least a portion of the output of said processor, and said data collection station to collect at least a portion of said response information.</p>
--	--

Application Claim 152	U.S. Pat. No. 5,233,654, Claim 33
<p>152. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</p> <p>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</p> <p>transferring said downloadable processor instructions to a transmitter;</p>	<p>33. In a method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to a detected instruct-to-respond signal;</p>

<p>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, at least one of said some is programmed to process information it holds in response to an instruct-to-respond signal, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said transmission and output the corresponding mass medium programming, and information of the reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, the step of:</p> <p>transmitting to said plurality of audience stations an instruct-to-respond signal, thereby causing said selected audience station to detect the presence of said instruct-to-respond signal, combine information of said signal to at least one processor of said station, process its reaction information in response to said instruct-to-respond signal and output data that include response information other than said reaction information, said data collection station to receive at least a portion of the output of said processor, and said data collection station to collect at least a portion of said response information.</p>
---	--

Application Claim 157	U.S. Pat. No. 5,233,654, Claim 33
<p>157. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</p> <p>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</p> <p>receiving, at said origination transmitter station, one</p>	<p>33. In a method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data</p>

<p>or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</p> <p>transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>collection station, and with at least some of said audience stations having capacity to respond selectively to a detected instruct-to-respond signal; and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, at least one of said some is programmed to process information it holds in response to an instruct-to-respond signal, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said transmission and output the corresponding mass medium programming, and information of the reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, the step of:</p> <p>transmitting to said plurality of audience stations an instruct-to-respond signal, thereby causing said selected audience station to detect the presence of said instruct-to-respond signal, combine information of said signal to at least one processor of said station, process its reaction information in response to said instruct-to-respond signal and output data that include response information other than said reaction information, said data collection station to receive at least a portion of the output of said processor, and said data collection station to collect at least a portion of said response information.</p>
---	--

Application Claim 162	U.S. Pat. No. 5,233,654, Claim 33
<p>162. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of discrete signals, said method comprising the steps of:</p> <p>receiving a video image at a transmitter station;</p> <p>delivering said video image to a transmitter;</p> <p>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete</p>	<p>33. In a method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means</p>

<p>signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</p> <p>transferring said at least said first of said plurality of discrete signals to said transmitter; and</p> <p>transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to a detected instruct-to-respond signal; and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, at least one of said some is programmed to process information it holds in response to an instruct-to-respond signal, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said transmission and output the corresponding mass medium programming, and information of the reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, the step of:</p> <p>transmitting to said plurality of audience stations an instruct-to-respond signal, thereby causing said selected audience station to detect the presence of said instruct-to-respond signal, combine information of said signal to at least one processor of said station, process its reaction information in response to said instruct-to-respond signal and output data that include response information other than said reaction information, said data collection station to receive at least a portion of the output of said processor, and said data collection station to collect at least a portion of said response information.</p>
--	--

Application Claim 167	U.S. Pat. No. 5,233,654, Claim 33
<p>167. A method of outputting a video graphic presentation at a receiver station including:</p> <p>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</p> <p>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</p>	<p>33. In a method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium</p>

<p>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal of said downloadable code;</p> <p>passing said at least a first discrete signal of said downloadable code to at least one processor;</p> <p>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</p> <p>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</p> <p>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</p> <p>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to a detected instruct-to-respond signal; and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, at least one of said some is programmed to process information it holds in response to an instruct-to-respond signal, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said transmission and output the corresponding mass medium programming, and information of the reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, the step of:</p> <p>transmitting to said plurality of audience stations an instruct-to-respond signal, thereby causing said selected audience station to detect the presence of said instruct-to-respond signal, combine information of said signal to at least one processor of said station, process its reaction information in response to said instruct-to-respond signal and output data that include response information other than said reaction information, said data collection station to receive at least a portion of the output of said processor, and said data collection station to collect at least a portion of said response information.</p>
---	--

Application Claim 171	U.S. Pat. No. 5,233,654, Claim 33
<p>171. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor</p>	<p>33. In a method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its</p>

<p>instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:</p> <p style="padding-left: 2em;">receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</p> <p style="padding-left: 2em;">transferring said at least one discrete signal to a transmitter;</p> <p style="padding-left: 2em;">receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;</p> <p style="padding-left: 2em;">transferring said one or more control signals to said transmitter; and</p> <p style="padding-left: 2em;">transmitting a transmission comprising said at least one discrete signal and said one or more control signals,</p> <p style="padding-left: 2em;">wherein said method delivers said video graphic presentation.</p>	<p>audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to a detected instruct-to-respond signal; and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, at least one of said some is programmed to process information it holds in response to an instruct-to-respond signal, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said transmission and output the corresponding mass medium programming, and information of the reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, the step of:</p> <p style="padding-left: 2em;">transmitting to said plurality of audience stations an instruct-to-respond signal, thereby causing said selected audience station to detect the presence of said instruct-to-respond signal, combine information of said signal to at least one processor of said station, process its reaction information in response to said instruct-to-respond signal and output data that include response information other than said reaction information, said data collection station to receive at least a portion of the output of said processor, and said data collection station to collect at least a portion of said response information.</p>
---	--

Application Claim 175	U.S. Pat. No. 5,233,654, Claim 33
175. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of	33. In a method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of

<p>said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</p> <p>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</p> <p>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</p> <p>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to a detected instruct-to-respond signal; and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, at least one of said some is programmed to process information it holds in response to an instruct-to-respond signal, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said transmission and output the corresponding mass medium programming, and information of the reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, the step of:</p> <p>transmitting to said plurality of audience stations an instruct-to-respond signal, thereby causing said selected audience station to detect the presence of said instruct-to-respond signal, combine information of said signal to at least one processor of said station, process its reaction information in response to said instruct-to-respond signal and output data that include response information other than said reaction information, said data collection station to receive at least a portion of the output of said processor, and said data collection station to collect at least a portion of said response information.</p>
--	--

Application Claim 177	U.S. Pat. No. 5,233,654, Claim 33
177. A method of delivering a video graphic	33. In a method for collecting response information

presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:

receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;

delivering said received first completed full-screen video graphic image to a transmitter;

receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;

transferring said one or more instruct signals to said transmitter; and

transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,

wherein said method delivers said video graphic presentation.

in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to a detected instruct-to-respond signal; and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, at least one of said some is programmed to process information it holds in response to an instruct-to-respond signal, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said transmission and output the corresponding mass medium programming, and information of the reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, the step of:

transmitting to said plurality of audience stations an instruct-to-respond signal, thereby causing said selected audience station to detect the presence of said instruct-to-respond signal, combine information of said signal to at least one processor of said station, process its reaction information in response to said instruct-to-respond signal and output data that include response information other than said reaction information, said data collection station to receive at least a portion of the output of said processor, and said data collection station to collect at least a portion of said response information.

Application Claim 179	U.S. Pat. No. 5,233,654, Claim 33
<p>179. A method of outputting a video graphic presentation at a receiver station including:</p> <ul style="list-style-type: none"> receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image; passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen; displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen; detecting said at least a first discrete signal; passing said at least a first discrete signal to at least one processor; organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal; responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing; passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image, <p>wherein said method delivers said video graphic presentation.</p>	<p>33. In a method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to a detected instruct-to-respond signal; and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, at least one of said some is programmed to process information it holds in response to an instruct-to-respond signal, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said transmission and output the corresponding mass medium programming, and information of the reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, the step of:</p> <ul style="list-style-type: none"> transmitting to said plurality of audience stations an instruct-to-respond signal, thereby causing said selected audience station to detect the presence of said instruct-to-respond signal, combine information of said signal to at least one processor of said station, process its reaction information in response to said instruct-to-respond signal and output data that include response information other than said reaction information, said data collection station to receive at least a portion of the output of said processor, and said data collection station to collect at least a portion

	of said response information.
--	-------------------------------

Application Claim 56	U.S. Pat. No. 5,233,654, Claim 34
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p><u>and</u></p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>34. A receiver station system for processing, recording, and transferring information of a member of a broadcast program audience to at least one remote data collection station comprising</p> <p>memory means for storing first information of said member,</p> <p>first processor means for processing said first information and assembling output records that include additional information besides said first information,</p> <p>recorder means for storing said output records,</p> <p>transmission means for transmitting at least some output of said recorder to said data collection station,</p> <p>detector means for detecting in a broadcast transmission at least one instruction, and</p> <p>second processor means operatively connected to said transmission means and said detector means for causing said transmission means to transmit said output in response to said instruction.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 5,233,654, Claim 34
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable</u></p>	<p>34. A receiver station system for processing, recording, and transferring information of a member of a broadcast program audience to at least one remote data collection station comprising</p> <p>memory means for storing first information of said member,</p> <p>first processor means for processing said first information and assembling output records that include additional information besides said first information,</p> <p>recorder means for storing said output records,</p> <p>transmission means for transmitting at least some output of said recorder to said data collection station,</p> <p>detector means for detecting in a broadcast transmission at least one instruction, and</p> <p>second processor means operatively connected to said transmission means and said detector means for causing said transmission means to transmit said output in response to said instruction.</p>

<p>processor instructions having at said at least one receiver station a target processor to process data; transferring said downloadable processor instructions to a transmitter; receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation; transferring said at least one control signal to said transmitter; and transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	
---	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 5,233,654, Claim 34
<p>80. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u></p> <p>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</p> <p>transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>34. A receiver station system for processing, recording, and transferring information of a member of a broadcast program audience to at least one remote data collection station comprising</p> <p>memory means for storing first information of said member,</p> <p>first processor means for processing said first information and assembling output records that include additional information besides said first information,</p> <p>recorder means for storing said output records,</p> <p>transmission means for transmitting at least some output of said recorder to said data collection station,</p> <p>detector means for detecting in a broadcast transmission at least one instruction, and</p> <p>second processor means operatively connected to said transmission means and said detector means for causing said transmission means to transmit said output in response to said instruction.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 5,233,654, Claim 34
<p>84. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, <u>wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals</u> and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving video at a transmitter station; delivering said video to a transmitter; <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and transmitting said video and said first discrete signal to said at least one receiver station. 	<p>34. A receiver station system for processing, recording, and transferring information of a member of a broadcast program audience to at least one remote data collection station comprising</p> <ul style="list-style-type: none"> memory means for storing first information of said member, first processor means for processing said first information and assembling output records that include additional information besides said first information, recorder means for storing said output records, transmission means for transmitting at least some output of said recorder to said data collection station, detector means for detecting in a broadcast transmission at least one instruction, and second processor means operatively connected to said transmission means and said detector means for causing said transmission means to transmit said output in response to said instruction.

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 5,233,654, Claim 34
<p>93. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete 	<p>34. A receiver station system for processing, recording, and transferring information of a member of a broadcast program audience to at least one remote data collection station comprising</p> <ul style="list-style-type: none"> memory means for storing first information of said member, first processor means for processing said first information and assembling output records that

<p>signal and at least one control signal; detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission; passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor; <u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; <u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>include additional information besides said first information, recorder means for storing said output records, transmission means for transmitting at least some output of said recorder to said data collection station, detector means for detecting in a broadcast transmission at least one instruction, and second processor means operatively connected to said transmission means and said detector means for causing said transmission means to transmit said output in response to said instruction.</p>
--	--

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 5,233,654, Claim 34
<p>110. A method of <u>outputting a video presentation</u> at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of: <u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said</u></p>	<p>34. A receiver station system for processing, recording, and transferring information of a member of a broadcast program audience to at least one remote data collection station comprising memory means for storing first information of said member, first processor means for processing said first information and assembling output records that include additional information besides said first information, recorder means for storing said output records, transmission means for transmitting at least some output of said recorder to said data collection station, detector means for detecting in a broadcast transmission at least one instruction, and second processor means operatively connected to said transmission means and said detector means for</p>

<p><u>at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u> transferring said at least said first discrete signal to at least one transmitter; <u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u> transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>causing said transmission means to transmit said output in response to said instruction.</p>
--	---

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 5,233,654, Claim 34
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u> <u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u> receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction; transferring said at least one control signal to said at</p>	<p>34. A receiver station system for processing, recording, and transferring information of a member of a broadcast program audience to at least one remote data collection station comprising memory means for storing first information of said member, first processor means for processing said first information and assembling output records that include additional information besides said first information, recorder means for storing said output records, transmission means for transmitting at least some output of said recorder to said data collection station, detector means for detecting in a broadcast transmission at least one instruction, and second processor means operatively connected to said transmission means and said detector means for causing said transmission means to transmit said output in response to said instruction.</p>

least one origination transmitter before a specific time; and transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.	
--	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 5,233,654, Claim 34
<p>123. A method of <u>delivering a video presentation</u> at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p>transferring said at least one instruct signal to at least one transmitter;</p> <p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to</u></p>	<p>34. A receiver station system for processing, recording, and transferring information of a member of a broadcast program audience to at least one remote data collection station comprising</p> <p>memory means for storing first information of said member,</p> <p>first processor means for processing said first information and assembling output records that include additional information besides said first information,</p> <p>recorder means for storing said output records,</p> <p>transmission means for transmitting at least some output of said recorder to said data collection station,</p> <p>detector means for detecting in a broadcast transmission at least one instruction, and</p> <p>second processor means operatively connected to said transmission means and said detector means for causing said transmission means to transmit said output in response to said instruction.</p>

<p>be effective at said at least one of said plurality of receiver stations; and</p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	
---	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 5,233,654, Claim 34
<p>142. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction;</u> and</p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>34. A receiver station system for processing, recording, and transferring information of a member of a broadcast program audience to at least one remote data collection station comprising</p> <p>memory means for storing first information of said member,</p> <p>first processor means for processing said first information and assembling output records that include additional information besides said first information,</p> <p>recorder means for storing said output records,</p> <p>transmission means for transmitting at least some output of said recorder to said data collection station,</p> <p>detector means for detecting in a broadcast transmission at least one instruction, and</p> <p>second processor means operatively connected to said transmission means and said detector means for causing said transmission means to transmit said output in response to said instruction.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 5,233,654, Claim 34
<p>143. <u>A method of outputting a video presentation</u> at a receiver station including:</p> <ul style="list-style-type: none"> receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to <u>processor instructions comprising said organized information,</u> based on said step of organizing; generating a signal based on said processor instructions; and outputting at least a portion of said video presentation based on said generated signal. 	<p>34. A receiver station system for processing, recording, and transferring information of a member of a broadcast program audience to at least one remote data collection station comprising</p> <ul style="list-style-type: none"> memory means for storing first information of said member, first processor means for processing said first information and assembling output records that include additional information besides said first information, recorder means for storing said output records, transmission means for transmitting at least some output of said recorder to said data collection station, detector means for detecting in a broadcast transmission at least one instruction, and second processor means operatively connected to said transmission means and said detector means for causing said transmission means to transmit said output in response to said instruction.

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 5,233,654, Claim 34
<p>152. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process <u>downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation</u> and have a target processor to process data, <u>said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station,</u> said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions; transferring said downloadable processor 	<p>34. A receiver station system for processing, recording, and transferring information of a member of a broadcast program audience to at least one remote data collection station comprising</p> <ul style="list-style-type: none"> memory means for storing first information of said member, first processor means for processing said first information and assembling output records that include additional information besides said first information, recorder means for storing said output records, transmission means for transmitting at least some output of said recorder to said data collection station, detector means for detecting in a broadcast transmission at least one instruction, and second processor means operatively connected to said transmission means and said detector means for causing said transmission means to transmit said output in response to said instruction.

<p>instructions to a transmitter;</p> <p><u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	
--	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 5,233,654, Claim 34
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</p> <p>transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>34. A receiver station system for processing, recording, and transferring information of a member of a broadcast program audience to at least one remote data collection station comprising</p> <p>memory means for storing first information of said member,</p> <p>first processor means for processing said first information and assembling output records that include additional information besides said first information,</p> <p>recorder means for storing said output records,</p> <p>transmission means for transmitting at least some output of said recorder to said data collection station,</p> <p>detector means for detecting in a broadcast transmission at least one instruction, and</p> <p>second processor means operatively connected to said transmission means and said detector means for causing said transmission means to transmit said output in response to said instruction.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 5,233,654, Claim 34
<p>162. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals</u>, said method comprising the steps of:</u></p> <p style="padding-left: 40px;">receiving a video image at a transmitter station; delivering said video image to a transmitter; <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u></p> <p style="padding-left: 40px;">transferring said at least said first of said plurality of discrete signals to said transmitter; and transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>34. A receiver station system for processing, recording, and transferring information of a member of a broadcast program audience to at least one remote data collection station comprising</p> <p style="padding-left: 40px;">memory means for storing first information of said member,</p> <p style="padding-left: 40px;">first processor means for processing said first information and assembling output records that include additional information besides said first information,</p> <p style="padding-left: 40px;">recorder means for storing said output records,</p> <p style="padding-left: 40px;">transmission means for transmitting at least some output of said recorder to said data collection station,</p> <p style="padding-left: 40px;">detector means for detecting in a broadcast transmission at least one instruction, and</p> <p style="padding-left: 40px;">second processor means operatively connected to said transmission means and said detector means for causing said transmission means to transmit said output in response to said instruction.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus.

Application Claim 167	U.S. Pat. No. 5,233,654, Claim 34
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u></p> <p style="padding-left: 40px;">receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-</p>	<p>34. A receiver station system for processing, recording, and transferring information of a member of a broadcast program audience to at least one remote data collection station comprising</p> <p style="padding-left: 40px;">memory means for storing first information of said</p>

<p>screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</p> <p>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal of said downloadable code;</p> <p>passing said at least a first discrete signal of said downloadable code to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u></p> <p><u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u></p> <p>wherein said method delivers said video graphic presentation.</p>	<p>member,</p> <p>first processor means for processing said first information and assembling output records that include additional information besides said first information,</p> <p>recorder means for storing said output records,</p> <p>transmission means for transmitting at least some output of said recorder to said data collection station,</p> <p>detector means for detecting in a broadcast transmission at least one instruction, and</p> <p>second processor means operatively connected to said transmission means and said detector means for causing said transmission means to transmit said output in response to said instruction.</p>
--	--

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 5,233,654, Claim 34
171. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is	34. A receiver station system for processing, recording, and transferring information of a member of a broadcast program audience to at least one remote data collection station comprising memory means for storing first information of said member, first processor means for processing said first

<p>programmed to process said at least one processor instruction, <u>wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:</u></p> <p><u>receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</u></p> <p>transferring said at least one discrete signal to a transmitter;</p> <p><u>receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said at least one discrete signal and said one or more control signals,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>information and assembling output records that include additional information besides said first information,</p> <p>recorder means for storing said output records,</p> <p>transmission means for transmitting at least some output of said recorder to said data collection station,</p> <p>detector means for detecting in a broadcast transmission at least one instruction, and</p> <p>second processor means operatively connected to said transmission means and said detector means for causing said transmission means to transmit said output in response to said instruction.</p>
--	---

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 5,233,654, Claim 34
<p>175. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</p> <p>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>34. A receiver station system for processing, recording, and transferring information of a member of a broadcast program audience to at least one remote data collection station comprising</p> <p>memory means for storing first information of said member,</p> <p>first processor means for processing said first information and assembling output records that include additional information besides said first information,</p> <p>recorder means for storing said output records,</p> <p>transmission means for transmitting at least some output of said recorder to said data collection station,</p> <p>detector means for detecting in a broadcast transmission at least one instruction, and</p> <p>second processor means operatively connected to said transmission means and said detector means for causing said transmission means to transmit said output in response to said instruction.</p>

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 5,233,654, Claim 34
<p>177. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>transferring said one or more instruct signals to said transmitter; and</p> <p>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>34. A receiver station system for processing, recording, and transferring information of a member of a broadcast program audience to at least one remote data collection station comprising</p> <p>memory means for storing first information of said member,</p> <p>first processor means for processing said first information and assembling output records that include additional information besides said first information,</p> <p>recorder means for storing said output records,</p> <p>transmission means for transmitting at least some output of said recorder to said data collection station,</p> <p>detector means for detecting in a broadcast transmission at least one instruction, and</p> <p>second processor means operatively connected to said transmission means and said detector means for causing said transmission means to transmit said output in response to said instruction.</p>

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 5,233,654, Claim 34
<p>179. <u>A method of outputting a video graphic presentation</u> at a receiver station including:</p> <p>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</p> <p>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal;</p> <p>passing said at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image;</u> and</p> <p><u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u></p> <p>wherein said method delivers said video graphic presentation.</p>	<p>34. A receiver station system for processing, recording, and transferring information of a member of a broadcast program audience to at least one remote data collection station comprising</p> <p>memory means for storing first information of said member,</p> <p>first processor means for processing said first information and assembling output records that include additional information besides said first information,</p> <p>recorder means for storing said output records,</p> <p>transmission means for transmitting at least some output of said recorder to said data collection station,</p> <p>detector means for detecting in a broadcast transmission at least one instruction, and</p> <p>second processor means operatively connected to said transmission means and said detector means for causing said transmission means to transmit said output in response to said instruction.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus.

Application Claim 56	U.S. Pat. No. 5,233,654, Claim 37
<p>56. A method for receiving and processing data for use with an interactive video apparatus, <u>said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source</u>, said method comprising the steps of:</p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p>communicating one of said at least said first request and a second request to a remote data source;</p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p>and</p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>37. In a method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to a detected instruct-to-respond signal; and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said transmission and output the corresponding mass medium programming, a transmission stations transmits to said plurality of audience stations an instruct-to-respond signal, information of the reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, and the presence of said instruct-to-respond signal is detected at said selected audience station and information of said signal is combined to at least one processor of said station, the step of:</p> <p>programming said selected station to process information it holds in response to an instruct-to-respond signal, thereby to cause said station to process its reaction information in response to said instruct-to-respond signal and output data that include response information other than said reaction information, and said data collection station to receive at least a portion of the output of said processor and collect at least a portion said response information.</p>

Application Claim 75	U.S. Pat. No. 5,233,654, Claim 37
<p>75. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, <u>said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image</u>, said method comprising the steps of:</p> <p style="padding-left: 2em;"><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image</u>, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</p> <p style="padding-left: 2em;">transferring said downloadable processor instructions to a transmitter;</p> <p style="padding-left: 2em;">receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</p> <p style="padding-left: 2em;">transferring said at least one control signal to said transmitter; and</p> <p style="padding-left: 2em;">transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	<p>37. In a method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to a detected instruct-to-respond signal; and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said transmission and output the corresponding mass medium programming, a transmission stations transmits to said plurality of audience stations an instruct-to-respond signal, information of the reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, and the presence of said instruct-to-respond signal is detected at said selected audience station and information of said signal is combined to at least one processor of said station, the step of:</p> <p style="padding-left: 2em;">programming said selected station to process information it holds in response to an instruct-to-respond signal, thereby to cause said station to process its reaction information in response to said instruct-to-respond signal and output data that include response information other than said reaction information, and</p>

	said data collection station to receive at least a portion of the output of said processor and collect at least a portion said response information.
--	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations in an operating environment of a receiver station .

Application Claim 80	U.S. Pat. No. 5,233,654, Claim 37
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u></p> <p style="padding-left: 20px;">receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</p> <p style="padding-left: 20px;"><u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u></p> <p style="padding-left: 20px;">receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</p> <p style="padding-left: 20px;">transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>37. In a method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to a detected instruct-to-respond signal; and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said transmission and output the corresponding mass medium programming, a transmission stations transmits to said plurality of audience stations an instruct-to-respond signal, information of the reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, and the presence of said instruct-to-respond signal is detected at said selected audience station and information of said signal is</p>

	<p>combined to at least one processor of said station, the step of:</p> <p>programming said selected station to process information it holds in response to an instruct-to-respond signal, thereby to cause said station to process its reaction information in response to said instruct-to-respond signal and output data that include response information other than said reaction information, and said data collection station to receive at least a portion of the output of said processor and collect at least a portion said response information.</p>
--	--

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations in an operating environment of a receiver station .

Application Claim 84	U.S. Pat. No. 5,233,654, Claim 37
<p>84. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, <u>wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals</u> and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <p style="padding-left: 40px;">receiving video at a transmitter station;</p> <p style="padding-left: 40px;">delivering said video to a transmitter;</p> <p style="padding-left: 40px;"><u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u></p> <p style="padding-left: 40px;">transferring said first discrete signal to said transmitter; and</p> <p style="padding-left: 40px;">transmitting said video and said first discrete signal to said at least one receiver station.</p>	<p>37. In a method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to a detected instruct-to-respond signal; and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said transmission and output the corresponding mass medium programming, a transmission stations transmits to said plurality of audience stations an instruct-to-respond signal,</p>

	<p>information of the reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, and the presence of said instruct-to-respond signal is detected at said selected audience station and information of said signal is combined to at least one processor of said station, the step of:</p> <p style="padding-left: 40px;">programming said selected station to process information it holds in response to an instruct-to-respond signal, thereby to cause said station to process its reaction information in response to said instruct-to-respond signal and output data that include response information other than said reaction information, and said data collection station to receive at least a portion of the output of said processor and collect at least a portion said response information.</p>
--	---

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations in an operating environment of a receiver station .

Application Claim 93	U.S. Pat. No. 5,233,654, Claim 37
<p>93. A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <p style="padding-left: 40px;">receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal;</p> <p style="padding-left: 40px;">detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission;</p> <p style="padding-left: 40px;">passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor;</p> <p style="padding-left: 40px;"><u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p style="padding-left: 40px;">passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p>	<p>37. In a method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission; one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to a detected instruct-to-respond signal; and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions</p>

<p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>to instruction signals associated with a mass medium programming transmission, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said transmission and output the corresponding mass medium programming, a transmission stations transmits to said plurality of audience stations an instruct-to-respond signal, information of the reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, and the presence of said instruct-to-respond signal is detected at said selected audience station and information of said signal is combined to at least one processor of said station, the step of:</p> <p>programming said selected station to process information it holds in response to an instruct-to-respond signal, thereby to cause said station to process its reaction information in response to said instruct-to-respond signal and output data that include response information other than said reaction information, and said data collection station to receive at least a portion of the output of said processor and collect at least a portion said response information.</p>
---	--

Application Claim 110	U.S. Pat. No. 5,233,654, Claim 37
<p>110. <u>A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</u></p> <p><u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u></p>	<p>37. In a method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to a detected instruct-to-respond signal;</p>

<p>transferring said at least said first discrete signal to at least one transmitter;</p> <p><u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u></p> <p>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said transmission and output the corresponding mass medium programming, a transmission stations transmits to said plurality of audience stations an instruct-to-respond signal, information of the reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, and the presence of said instruct-to-respond signal is detected at said selected audience station and information of said signal is combined to at least one processor of said station, the step of:</p> <p>programming said selected station to process information it holds in response to an instruct-to-respond signal, thereby to cause said station to process its reaction information in response to said instruct-to-respond signal and output data that include response information other than said reaction information, and said data collection station to receive at least a portion of the output of said processor and collect at least a portion said response information.</p>
---	--

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations in an operating environment of a receiver station .

Application Claim 116	U.S. Pat. No. 5,233,654, Claim 37
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u></p>	<p>37. In a method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for</p>

<p><u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u></p> <p>receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</p> <p>transferring said at least one control signal to said at least one origination transmitter before a specific time; and</p> <p>transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	<p>processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to a detected instruct-to-respond signal; and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said transmission and output the corresponding mass medium programming, a transmission stations transmits to said plurality of audience stations an instruct-to-respond signal, information of the reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, and the presence of said instruct-to-respond signal is detected at said selected audience station and information of said signal is combined to at least one processor of said station, the step of:</p> <p>programming said selected station to process information it holds in response to an instruct-to-respond signal, thereby to cause said station to process its reaction information in response to said instruct-to-respond signal and output data that include response information other than said reaction information, and said data collection station to receive at least a portion of the output of said processor and collect at least a portion said response information.</p>
---	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 123	U.S. Pat. No. 5,233,654, Claim 37
123. <u>A method of delivering a video presentation</u> at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said	37. In a method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection

plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:

receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;

transferring said at least one instruct signal to at least one transmitter;

receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and

transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.

station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to a detected instruct-to-respond signal; and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said transmission and output the corresponding mass medium programming, a transmission stations transmits to said plurality of audience stations an instruct-to-respond signal, information of the reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, and the presence of said instruct-to-respond signal is detected at said selected audience station and information of said signal is combined to at least one processor of said station, the step of:

programming said selected station to process information it holds in response to an instruct-to-respond signal, thereby to cause said station to process its reaction information in response to said instruct-to-respond signal and output data that include response information other than said reaction information, and said data collection station to receive at least a portion of the output of said processor and collect at least a portion said response information.

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates

claim 123 over the patented claim's recitations in an operating environment of a receiver station

Application Claim 142	U.S. Pat. No. 5,233,654, Claim 37
<p>142. A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction;</u> and</p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>37. In a method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to a detected instruct-to-respond signal; and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said transmission and output the corresponding mass medium programming, a transmission stations transmits to said plurality of audience stations an instruct-to-respond signal, information of the reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, and the presence of said instruct-to-respond signal is detected at said selected audience station and information of said signal is combined to at least one processor of said station, the step of:</p> <p>programming said selected station to process information it holds in response to an instruct-to-respond signal, thereby to cause said station to process its reaction information in response to said instruct-to-</p>

	respond signal and output data that include response information other than said reaction information, and said data collection station to receive at least a portion of the output of said processor and collect at least a portion said response information.
--	---

Application Claim 143	U.S. Pat. No. 5,233,654, Claim 37
<p>143. A method of outputting a video presentation at a receiver station including:</p> <ul style="list-style-type: none"> receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal; responding, at said processor, to processor instructions comprising said organized information, based on said step of organizing; generating a signal based on said processor instructions; and outputting at least a portion of said video presentation based on said generated signal. 	<p>37. In a method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to a detected instruct-to-respond signal; and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said transmission and output the corresponding mass medium programming, a transmission stations transmits to said plurality of audience stations an instruct-to-respond signal, information of the reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, and the presence of said instruct-to-respond signal is detected at said selected audience station and information of said signal is combined to at least one processor of said station, the step of:</p> <p style="padding-left: 20px;">programming said selected station to process</p>

	information it holds in response to an instruct-to-respond signal, thereby to cause said station to process its reaction information in response to said instruct-to-respond signal and output data that include response information other than said reaction information, and said data collection station to receive at least a portion of the output of said processor and collect at least a portion said response information.

Application Claim 152	U.S. Pat. No. 5,233,654, Claim 37
<p>152. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process <u>downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation</u> and have a target processor to process data, <u>said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station</u>, said method comprising the steps of:</p> <p style="padding-left: 40px;">receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</p> <p style="padding-left: 40px;">transferring said downloadable processor instructions to a transmitter;</p> <p style="padding-left: 40px;">receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and <u>wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image</u>;</p> <p style="padding-left: 40px;">transferring said one or more control signals to said transmitter; and</p> <p style="padding-left: 40px;">transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>37. In a method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to a detected instruct-to-respond signal; and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said transmission and output the corresponding mass medium programming, a transmission stations transmits to said plurality of audience stations an instruct-to-respond signal, information of the reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, and the presence of said instruct-to-respond signal is detected at said selected audience station and information of said signal is</p>

	<p>combined to at least one processor of said station, the step of:</p> <p>programming said selected station to process information it holds in response to an instruct-to-respond signal, thereby to cause said station to process its reaction information in response to said instruct-to-respond signal and output data that include response information other than said reaction information, and said data collection station to receive at least a portion of the output of said processor and collect at least a portion said response information.</p>
--	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations in an operating environment of a receiver station

Application Claim 157	U.S. Pat. No. 5,233,654, Claim 37
<p>157. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</p> <p>transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>37. In a method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to a detected instruct-to-respond signal; and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said transmission and output the corresponding mass medium programming, a transmission stations transmits to said plurality of audience stations an instruct-to-respond signal,</p>

	<p>information of the reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, and the presence of said instruct-to-respond signal is detected at said selected audience station and information of said signal is combined to at least one processor of said station, the step of:</p> <p style="padding-left: 40px;">programming said selected station to process information it holds in response to an instruct-to-respond signal, thereby to cause said station to process its reaction information in response to said instruct-to-respond signal and output data that include response information other than said reaction information, and said data collection station to receive at least a portion of the output of said processor and collect at least a portion said response information.</p>
--	---

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations in an operating environment of a receiver station

Application Claim 162	U.S. Pat. No. 5,233,654, Claim 37
<p>162. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of discrete signals, said method comprising the steps of:</u></p> <p style="padding-left: 40px;"><u>receiving a video image at a transmitter station;</u></p> <p style="padding-left: 40px;"><u>delivering said video image to a transmitter;</u></p> <p style="padding-left: 40px;"><u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u></p>	<p>37. In a method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to a detected instruct-to-respond signal; and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions</p>

<p>transferring said at least said first of said plurality of discrete signals to said transmitter; and transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>to instruction signals associated with a mass medium programming transmission, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said transmission and output the corresponding mass medium programming, a transmission stations transmits to said plurality of audience stations an instruct-to-respond signal, information of the reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, and the presence of said instruct-to-respond signal is detected at said selected audience station and information of said signal is combined to at least one processor of said station, the step of: programming said selected station to process information it holds in response to an instruct-to-respond signal, thereby to cause said station to process its reaction information in response to said instruct-to-respond signal and output data that include response information other than said reaction information, and said data collection station to receive at least a portion of the output of said processor and collect at least a portion said response information.</p>
---	---

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations in an operating environment of a receiver station

Application Claim 167	U.S. Pat. No. 5,233,654, Claim 37
<p>167. A method of outputting a video graphic presentation at a receiver station including: receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image; passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen; displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p>	<p>37. In a method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that</p>

<p>detecting said at least a first discrete signal of said downloadable code;</p> <p>passing said at least a first discrete signal of said downloadable code to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u></p> <p><u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u></p> <p>wherein said method delivers said video graphic presentation.</p>	<p>control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to a detected instruct-to-respond signal; and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said transmission and output the corresponding mass medium programming, a transmission stations transmits to said plurality of audience stations an instruct-to-respond signal, information of the reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, and the presence of said instruct-to-respond signal is detected at said selected audience station and information of said signal is combined to at least one processor of said station, the step of:</p> <p>programming said selected station to process information it holds in response to an instruct-to-respond signal, thereby to cause said station to process its reaction information in response to said instruct-to-respond signal and output data that include response information other than said reaction information, and said data collection station to receive at least a portion of the output of said processor and collect at least a portion said response information.</p>
--	---

Application Claim 171	U.S. Pat. No. 5,233,654, Claim 37
<p>171. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein</u></p>	<p>37. In a method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for</p>

<p><u>said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image,</u> said method comprising the steps of:</p> <p style="padding-left: 20px;"><u>receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</u></p> <p style="padding-left: 20px;">transferring said at least one discrete signal to a transmitter;</p> <p style="padding-left: 20px;"><u>receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;</u></p> <p style="padding-left: 20px;">transferring said one or more control signals to said transmitter; and</p> <p style="padding-left: 20px;">transmitting a transmission comprising said at least one discrete signal and said one or more control signals,</p> <p style="padding-left: 20px;">wherein said method delivers said video graphic presentation.</p>	<p>processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to a detected instruct-to-respond signal; and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said transmission and output the corresponding mass medium programming, a transmission stations transmits to said plurality of audience stations an instruct-to-respond signal, information of the reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, and the presence of said instruct-to-respond signal is detected at said selected audience station and information of said signal is combined to at least one processor of said station, the step of:</p> <p style="padding-left: 20px;">programming said selected station to process information it holds in response to an instruct-to-respond signal, thereby to cause said station to process its reaction information in response to said instruct-to-respond signal and output data that include response information other than said reaction information, and said data collection station to receive at least a portion of the output of said processor and collect at least a portion said response information.</p>
--	--

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations in an operating environment of a receiver station

Application Claim 175	U.S. Pat. No. 5,233,654, Claim 37
175. <u>A method of delivering a video graphic presentation at at least one receiver station of a</u>	37. In a method for collecting response information in a system that consists of at least one mass medium

plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:

receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;

delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;

receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and

transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,

wherein said method delivers said video graphic presentation.

programming transmission station, a plurality of audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to a detected instruct-to-respond signal; and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said transmission and output the corresponding mass medium programming, a transmission stations transmits to said plurality of audience stations an instruct-to-respond signal, information of the reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, and the presence of said instruct-to-respond signal is detected at said selected audience station and information of said signal is combined to at least one processor of said station, the step of:

programming said selected station to process information it holds in response to an instruct-to-respond signal, thereby to cause said station to process its reaction information in response to said instruct-to-respond signal and output data that include response information other than said reaction information, and said data collection station to receive at least a portion of the output of said processor and collect at least a portion said response information.

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter

station and a receiver station. This differentiates claim 175 over the patented claim's recitations in an operating environment of a receiver station

Application Claim 177	U.S. Pat. No. 5,233,654, Claim 37
<p>177. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>transferring said one or more instruct signals to said transmitter; and</p> <p>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>37. In a method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to a detected instruct-to-respond signal; and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said transmission and output the corresponding mass medium programming, a transmission stations transmits to said plurality of audience stations an instruct-to-respond signal, information of the reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, and the presence of said instruct-to-respond signal is detected at said selected audience station and information of said signal is combined to at least one processor of said station, the step of:</p> <p>programming said selected station to process information it holds in response to an instruct-to-respond signal, thereby to cause said station to process its reaction information in response to said instruct-to-respond signal and output data that include response information other than said reaction information, and</p>

	said data collection station to receive at least a portion of the output of said processor and collect at least a portion said response information.
--	--

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations in an operating environment of a receiver station

Application Claim 179	U.S. Pat. No. 5,233,654, Claim 37
<p>179. A method of outputting a video graphic presentation at a receiver station including:</p> <ul style="list-style-type: none"> receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image; passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen; displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen; detecting said at least a first discrete signal; passing said at least a first discrete signal to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image;</u> and <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> wherein said method delivers said video graphic presentation. 	<p>37. In a method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to a detected instruct-to-respond signal; and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said transmission and output the corresponding mass medium programming, a transmission stations transmits to said plurality of audience stations an instruct-to-respond signal, information of the reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, and the presence of said instruct-to-respond signal is detected at said selected audience station and information of said signal is</p>

	<p>combined to at least one processor of said station, the step of:</p> <p>programming said selected station to process information it holds in response to an instruct-to-respond signal, thereby to cause said station to process its reaction information in response to said instruct-to-respond signal and output data that include response information other than said reaction information, and said data collection station to receive at least a portion of the output of said processor and collect at least a portion said response information.</p>
--	--

Application Claim 56	U.S. Pat. No. 5,233,654, Claim 38
<p>56. A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying <u>a video presentation comprising a locally generated image and an image received from a remote video source</u>, said method comprising the steps of:</p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p>and</p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>38. In a method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to detected instruct-to-respond signal; and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, at least one of said some is programmed to process information it holds in response to an instruct-to-respond signal, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said transmission and output the corresponding mass medium programming, a transmission stations transmits to said plurality of audience stations an instruct-to-respond signal, information of the reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, the presence of said instruct-to-respond signal is detected at said selected audience station and information of said signal is combined to at least one processor of said station, and said station is caused to process its reaction information in response to said instruct-to-respond signal and output data that include response information other than said reaction information, the step of:</p> <p>receiving at least a portion of the output of said processor at said data collection station, thereby to cause said data collection station to collect at least a</p>

	portion said response information.
--	------------------------------------

Application Claim 75	U.S. Pat. No. 5,233,654, Claim 38
<p>75. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, <u>said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image</u>, said method comprising the steps of:</p> <p style="padding-left: 20px;"><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image</u>, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</p> <p style="padding-left: 20px;">transferring said downloadable processor instructions to a transmitter;</p> <p style="padding-left: 20px;">receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</p> <p style="padding-left: 20px;">transferring said at least one control signal to said transmitter; and</p> <p style="padding-left: 20px;">transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	<p>38. In a method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to detected instruct-to-respond signal; and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, at least one of said some is programmed to process information it holds in response to an instruct-to-respond signal, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said transmission and output the corresponding mass medium programming, a transmission stations transmits to said plurality of audience stations an instruct-to-respond signal, information of the reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, the presence of said instruct-to-respond signal is detected at said selected audience station and information of said signal is combined to at least one processor of said station, and said station is caused to process its reaction information in response to said instruct-to-respond signal and output data that include response information other than said reaction information, the</p>

	<p>step of:</p> <p>receiving at least a portion of the output of said processor at said data collection station, thereby to cause said data collection station to collect at least a portion said response information.</p>
--	---

Application Claim 80	U.S. Pat. No. 5,233,654, Claim 38
<p>80. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u></p> <p>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</p> <p>transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>38. In a method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to detected instruct-to-respond signal; and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, at least one of said some is programmed to process information it holds in response to an instruct-to-respond signal, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said transmission and output the corresponding mass medium programming, a transmission stations transmits to said plurality of audience stations an instruct-to-respond signal, information of the reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, the presence of said instruct-to-respond signal is detected at said selected audience station and information of said signal is combined to at least one processor of</p>

	<p>said station, and said station is caused to process its reaction information in response to said instruct-to-respond signal and output data that include response information other than said reaction information, the step of:</p> <p style="padding-left: 40px;">receiving at least a portion of the output of said processor at said data collection station, thereby to cause said data collection station to collect at least a portion said response information.</p>
--	---

Application Claim 84	U.S. Pat. No. 5,233,654, Claim 38
<p>84. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, <u>wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals</u> and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <p style="padding-left: 40px;">receiving video at a transmitter station;</p> <p style="padding-left: 40px;">delivering said video to a transmitter;</p> <p style="padding-left: 40px;"><u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u></p> <p style="padding-left: 40px;">transferring said first discrete signal to said transmitter; and</p> <p style="padding-left: 40px;">transmitting said video and said first discrete signal to said at least one receiver station.</p>	<p>38. In a method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to detected instruct-to-respond signal; and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, at least one of said some is programmed to process information it holds in response to an instruct-to-respond signal, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said transmission and output the corresponding mass medium programming, a transmission stations transmits to said plurality of audience stations an instruct-to-respond signal, information of the reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with</p>

	<p>a mass medium programming transmission, the presence of said instruct-to-respond signal is detected at said selected audience station and information of said signal is combined to at least one processor of said station, and said station is caused to process its reaction information in response to said instruct-to-respond signal and output data that include response information other than said reaction information, the step of:</p> <p style="padding-left: 40px;">receiving at least a portion of the output of said processor at said data collection station, thereby to cause said data collection station to collect at least a portion said response information.</p>
--	---

Application Claim 93	U.S. Pat. No. 5,233,654, Claim 38
<p>93. A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <p style="padding-left: 40px;">receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal;</p> <p style="padding-left: 40px;">detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission;</p> <p style="padding-left: 40px;">passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor;</p> <p style="padding-left: 40px;"><u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p style="padding-left: 40px;">passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;</p> <p style="padding-left: 40px;">responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p style="padding-left: 40px;"><u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u></p> <p style="padding-left: 40px;"><u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>38. In a method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to detected instruct-to-respond signal; and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, at least one of said some is programmed to process information it holds in response to an instruct-to-respond signal, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said transmission and output the corresponding mass medium programming, a transmission stations transmits to said plurality of audience stations an instruct-to-respond signal, information of the reaction</p>

	<p>of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, the presence of said instruct-to-respond signal is detected at said selected audience station and information of said signal is combined to at least one processor of said station, and said station is caused to process its reaction information in response to said instruct-to-respond signal and output data that include response information other than said reaction information, the step of:</p> <p style="padding-left: 40px;">receiving at least a portion of the output of said processor at said data collection station, thereby to cause said data collection station to collect at least a portion said response information.</p>
--	--

Application Claim 110	U.S. Pat. No. 5,233,654, Claim 38
<p>110. A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</p> <p style="padding-left: 40px;"><u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u></p> <p style="padding-left: 40px;">transferring said at least said first discrete signal to at least one transmitter;</p> <p style="padding-left: 40px;"><u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u></p> <p style="padding-left: 40px;">transferring said at least one control signal to said at least one transmitter, and transmitting at least one</p>	<p>38. In a method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to detected instruct-to-respond signal; and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, at least one of said some is programmed to process information it holds in response to an instruct-to-respond signal, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said</p>

information transmission containing said at least said first discrete signal and said at least one control signal.	<p>transmission and output the corresponding mass medium programming, a transmission stations transmits to said plurality of audience stations an instruct-to-respond signal, information of the reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, the presence of said instruct-to-respond signal is detected at said selected audience station and information of said signal is combined to at least one processor of said station, and said station is caused to process its reaction information in response to said instruct-to-respond signal and output data that include response information other than said reaction information, the step of:</p> <p>receiving at least a portion of the output of said processor at said data collection station, thereby to cause said data collection station to collect at least a portion said response information.</p>
--	---

Application Claim 116	U.S. Pat. No. 5,233,654, Claim 38
<p>116. A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, <u>wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction</u>, said method comprising the steps of:</p> <p><u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u></p> <p>receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and</p>	<p>38. In a method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to detected instruct-to-respond signal; and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, at least one of said some is programmed to process information it holds in</p>

<p>said at least one processor instruction; transferring said at least one control signal to said at least one origination transmitter before a specific time; and transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	<p>response to an instruct-to-respond signal, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said transmission and output the corresponding mass medium programming, a transmission stations transmits to said plurality of audience stations an instruct-to-respond signal, information of the reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, the presence of said instruct-to-respond signal is detected at said selected audience station and information of said signal is combined to at least one processor of said station, and said station is caused to process its reaction information in response to said instruct-to-respond signal and output data that include response information other than said reaction information, the step of: receiving at least a portion of the output of said processor at said data collection station, thereby to cause said data collection station to collect at least a portion said response information.</p>
---	--

Application Claim 123	U.S. Pat. No. 5,233,654, Claim 38
<p>123. A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of: <u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u> transferring said at least one instruct signal to at least one transmitter;</p>	<p>38. In a method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to detected instruct-to-respond signal; and wherein at least some of said last named audience stations are programmed to hold information of an</p>

<p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and</u></p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	<p>audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, at least one of said some is programmed to process information it holds in response to an instruct-to-respond signal, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said transmission and output the corresponding mass medium programming, a transmission stations transmits to said plurality of audience stations an instruct-to-respond signal, information of the reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, the presence of said instruct-to-respond signal is detected at said selected audience station and information of said signal is combined to at least one processor of said station, and said station is caused to process its reaction information in response to said instruct-to-respond signal and output data that include response information other than said reaction information, the step of:</p> <p style="padding-left: 40px;">receiving at least a portion of the output of said processor at said data collection station, thereby to cause said data collection station to collect at least a portion said response information.</p>
---	---

Application Claim 142	U.S. Pat. No. 5,233,654, Claim 38
<p>142. A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p style="padding-left: 40px;">receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p style="padding-left: 40px;">detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p style="padding-left: 40px;">passing said detected at least a first discrete signal to at least one processor;</p> <p style="padding-left: 40px;"><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p style="padding-left: 40px;">passing at least one processor instruction from or within said at least one processor, said at least one</p>	<p>38. In a method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said</p>

<p>processor instruction comprising said organized information from said step of organizing; responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; <u>generating only a portion of said video image based on said step of responding to said at least one processor instruction;</u> and <u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>audience stations having capacity to respond selectively to detected instruct-to-respond signal; and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, at least one of said some is programmed to process information it holds in response to an instruct-to-respond signal, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said transmission and output the corresponding mass medium programming, a transmission stations transmits to said plurality of audience stations an instruct-to-respond signal, information of the reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, the presence of said instruct-to-respond signal is detected at said selected audience station and information of said signal is combined to at least one processor of said station, and said station is caused to process its reaction information in response to said instruct-to-respond signal and output data that include response information other than said reaction information, the step of: receiving at least a portion of the output of said processor at said data collection station, thereby to cause said data collection station to collect at least a portion said response information.</p>
---	--

Application Claim 143	U.S. Pat. No. 5,233,654, Claim 38
<p>143. A method of outputting a video presentation at a receiver station including: receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second</u></p>	<p>38. In a method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means</p>

<p><u>discrete signal:</u> responding, at said processor, to processor instructions comprising said organized information, based on said step of organizing; generating a signal based on said processor instructions; and <u>outputting at least a portion of said video presentation based on said generated signal.</u></p>	<p>capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to detected instruct-to-respond signal; and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, at least one of said some is programmed to process information it holds in response to an instruct-to-respond signal, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said transmission and output the corresponding mass medium programming, a transmission stations transmits to said plurality of audience stations an instruct-to-respond signal, information of the reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, the presence of said instruct-to-respond signal is detected at said selected audience station and information of said signal is combined to at least one processor of said station, and said station is caused to process its reaction information in response to said instruct-to-respond signal and output data that include response information other than said reaction information, the step of: receiving at least a portion of the output of said processor at said data collection station, thereby to cause said data collection station to collect at least a portion said response information.</p>
---	---

Application Claim 152	U.S. Pat. No. 5,233,654, Claim 38
<p>152. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process <u>downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation</u> and have a target processor to process data, <u>said video presentation</u></p>	<p>38. In a method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for</p>

<p><u>comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station</u>, said method comprising the steps of:</p> <p>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p><u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to detected instruct-to-respond signal; and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, at least one of said some is programmed to process information it holds in response to an instruct-to-respond signal, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said transmission and output the corresponding mass medium programming, a transmission stations transmits to said plurality of audience stations an instruct-to-respond signal, information of the reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, the presence of said instruct-to-respond signal is detected at said selected audience station and information of said signal is combined to at least one processor of said station, and said station is caused to process its reaction information in response to said instruct-to-respond signal and output data that include response information other than said reaction information, the step of:</p> <p>receiving at least a portion of the output of said processor at said data collection station, thereby to cause said data collection station to collect at least a portion said response information.</p>
---	--

Application Claim 157	U.S. Pat. No. 5,233,654, Claim 38
<p>157. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</p>	<p>38. In a method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass</p>

<p>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</p> <p>transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to detected instruct-to-respond signal; and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, at least one of said some is programmed to process information it holds in response to an instruct-to-respond signal, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said transmission and output the corresponding mass medium programming, a transmission stations transmits to said plurality of audience stations an instruct-to-respond signal, information of the reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, the presence of said instruct-to-respond signal is detected at said selected audience station and information of said signal is combined to at least one processor of said station, and said station is caused to process its reaction information in response to said instruct-to-respond signal and output data that include response information other than said reaction information, the step of:</p> <p>receiving at least a portion of the output of said processor at said data collection station, thereby to cause said data collection station to collect at least a portion said response information.</p>
---	--

Application Claim 162	U.S. Pat. No. 5,233,654, Claim 38
162. A method of delivering a video presentation at at least one receiver station of a plurality of receiver	38. In a method for collecting response information in a system that consists of at least one mass medium

stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of discrete signals, said method comprising the steps of:

- receiving a video image at a transmitter station;
- delivering said video image to a transmitter;
- receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;
- transferring said at least said first of said plurality of discrete signals to said transmitter; and
- transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.

programming transmission station, a plurality of audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to detected instruct-to-respond signal; and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, at least one of said some is programmed to process information it holds in response to an instruct-to-respond signal, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said transmission and output the corresponding mass medium programming, a transmission stations transmits to said plurality of audience stations an instruct-to-respond signal, information of the reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, the presence of said instruct-to-respond signal is detected at said selected audience station and information of said signal is combined to at least one processor of said station, and said station is caused to process its reaction information in response to said instruct-to-respond signal and output data that include response information other than said reaction information, the step of:

- receiving at least a portion of the output of said processor at said data collection station, thereby to cause said data collection station to collect at least a portion said response information.

Application Claim 167	U.S. Pat. No. 5,233,654, Claim 38
<p>167. A method of outputting a video graphic presentation at a receiver station including:</p> <p><u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</u></p> <p>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal of said downloadable code;</p> <p>passing said at least a first discrete signal of said downloadable code to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u></p> <p><u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u></p> <p>wherein said method delivers said video graphic presentation.</p>	<p>38. In a method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to detected instruct-to-respond signal; and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, at least one of said some is programmed to process information it holds in response to an instruct-to-respond signal, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said transmission and output the corresponding mass medium programming, a transmission stations transmits to said plurality of audience stations an instruct-to-respond signal, information of the reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, the presence of said instruct-to-respond signal is detected at said selected audience station and information of said signal is combined to at least one processor of said station, and said station is caused to process its reaction information in response to said instruct-to-respond signal and output data that include response information other than said reaction information, the step of:</p> <p>receiving at least a portion of the output of said processor at said data collection station, thereby to</p>

	cause said data collection station to collect at least a portion said response information.
--	---

Application Claim 171	U.S. Pat. No. 5,233,654, Claim 38
<p>171. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, <u>wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:</u></p> <p style="padding-left: 20px;"><u>receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</u></p> <p style="padding-left: 20px;">transferring said at least one discrete signal to a transmitter;</p> <p style="padding-left: 20px;"><u>receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;</u></p>	<p>38. In a method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to detected instruct-to-respond signal; and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, at least one of said some is programmed to process information it holds in response to an instruct-to-respond signal, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said transmission and output the corresponding mass medium programming, a transmission stations transmits to said plurality of audience stations an instruct-to-respond signal, information of the reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, the presence of said instruct-to-respond signal is detected at said selected audience station and information of said signal is combined to at least one processor of said station, and said station is caused to process its reaction information in response to said instruct-to-respond signal and output data that include response</p>

<p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said at least one discrete signal and said one or more control signals,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>information other than said reaction information, the step of:</p> <p>receiving at least a portion of the output of said processor at said data collection station, thereby to cause said data collection station to collect at least a portion said response information.</p>
--	---

Application Claim 175	U.S. Pat. No. 5,233,654, Claim 38
<p>175. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</p>	<p>38. In a method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to detected instruct-to-respond signal; and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, at least one of said some is programmed to process information it holds in response to an instruct-to-respond signal, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said transmission and output the corresponding mass medium programming, a transmission stations transmits to said plurality of audience stations an instruct-to-respond signal, information of the reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, the presence of said instruct-to-respond signal is detected</p>

<p>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>at said selected audience station and information of said signal is combined to at least one processor of said station, and said station is caused to process its reaction information in response to said instruct-to-respond signal and output data that include response information other than said reaction information, the step of:</p> <p>receiving at least a portion of the output of said processor at said data collection station, thereby to cause said data collection station to collect at least a portion said response information.</p>
--	---

Application Claim 177	U.S. Pat. No. 5,233,654, Claim 38
<p>177. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>transferring said one or more instruct signals to said transmitter; and</p> <p>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one</p>	<p>38. In a method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to detected instruct-to-respond signal; and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, at least one of said some is programmed to process information it holds in response to an instruct-to-respond signal, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said transmission and output the corresponding mass medium programming, a transmission stations transmits to said plurality of audience stations an instruct-to-respond signal, information of the reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in</p>

<p>receiver station, wherein said method delivers said video graphic presentation.</p>	<p>selected fashions to instruction signals associated with a mass medium programming transmission, the presence of said instruct-to-respond signal is detected at said selected audience station and information of said signal is combined to at least one processor of said station, and said station is caused to process its reaction information in response to said instruct-to-respond signal and output data that include response information other than said reaction information, the step of: receiving at least a portion of the output of said processor at said data collection station, thereby to cause said data collection station to collect at least a portion said response information.</p>
--	---

Application Claim 179	U.S. Pat. No. 5,233,654, Claim 38
<p>179. A method of outputting a video graphic presentation at a receiver station including: receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image; passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen; displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen; detecting said at least a first discrete signal; passing said at least a first discrete signal to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing; <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen</u></p>	<p>38. In a method for collecting response information in a system that consists of at least one mass medium programming transmission station, a plurality of audience stations, and at least one data collection station; with each audience station serving at least one audience member and including at least one mass medium programming receiver, one output means for outputting mass medium programming to its audience member, one input means for inputting information of said member, one detector means for detecting instructions associated with a mass medium programming transmission, one processor for processing information and controlling apparatus of said station in selected fashions, one memory means capable of holding programming instructions that control the operation of said processor, and one transmission means for transmitting data to said data collection station, and with at least some of said audience stations having capacity to respond selectively to detected instruct-to-respond signal; and wherein at least some of said last named audience stations are programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, at least one of said some is programmed to process information it holds in response to an instruct-to-respond signal, a transmission station transmits mass medium programming that elicits audience reactions, a plurality of said audience stations receive said transmission and output the corresponding mass medium programming, a transmission stations transmits to said plurality of audience stations an</p>

and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,

wherein said method delivers said video graphic presentation.

instruct-to-respond signal, information of the reaction of an audience member is inputted at a selected audience station that is programmed to hold information of an audience member and to respond in selected fashions to instruction signals associated with a mass medium programming transmission, the presence of said instruct-to-respond signal is detected at said selected audience station and information of said signal is combined to at least one processor of said station, and said station is caused to process its reaction information in response to said instruct-to-respond signal and output data that include response information other than said reaction information, the step of:

receiving at least a portion of the output of said processor at said data collection station, thereby to cause said data collection station to collect at least a portion said response information.

Application Claim 56	U.S. Pat. No. 5,233,654, Claim 59
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p>and</p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>59. A receiver station system for processing and recording information of a member of a broadcast program audience for at least one remote data collection station comprising</p> <p>input means for inputting member information,</p> <p>memory means for storing said input information,</p> <p>detector means for detecting in a broadcast transmission at least one instruction,</p> <p>processor means operatively connected to said memory means and said detector means for processing said input information in accordance with said instruction and assembling output records that include additional information besides said input information, and</p> <p>recorder means for storing said output records on a memory medium.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 5,233,654, Claim 59
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable</u></p>	<p>59. A receiver station system for processing and recording information of a member of a broadcast program audience for at least one remote data collection station comprising</p> <p>input means for inputting member information,</p> <p>memory means for storing said input information,</p> <p>detector means for detecting in a broadcast transmission at least one instruction,</p> <p>processor means operatively connected to said memory means and said detector means for processing said input information in accordance with said instruction and assembling output records that include additional information besides said input information, and</p> <p>recorder means for storing said output records on a memory medium.</p>

<p>processor instructions having at said at least one receiver station a target processor to process data; transferring said downloadable processor instructions to a transmitter; receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation; transferring said at least one control signal to said transmitter; and transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	
---	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 5,233,654, Claim 59
<p>80. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u></p> <p>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</p> <p>transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>59. A receiver station system for processing and recording information of a member of a broadcast program audience for at least one remote data collection station comprising</p> <p>input means for inputting member information, memory means for storing said input information, detector means for detecting in a broadcast transmission at least one instruction, processor means operatively connected to said memory means and said detector means for processing said input information in accordance with said instruction and assembling output records that include additional information besides said input information, and</p> <p>recorder means for storing said output records on a memory medium.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 5,233,654, Claim 59
<p>84. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, <u>wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals</u> and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving video at a transmitter station; delivering said video to a transmitter; <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and transmitting said video and said first discrete signal to said at least one receiver station. 	<p>59. A receiver station system for processing and recording information of a member of a broadcast program audience for at least one remote data collection station comprising</p> <ul style="list-style-type: none"> input means for inputting member information, memory means for storing said input information, detector means for detecting in a broadcast transmission at least one instruction, processor means operatively connected to said memory means and said detector means for processing said input information in accordance with said instruction and assembling output records that include additional information besides said input information, and recorder means for storing said output records on a memory medium.

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 5,233,654, Claim 59
<p>93. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete 	<p>59. A receiver station system for processing and recording information of a member of a broadcast program audience for at least one remote data collection station comprising</p> <ul style="list-style-type: none"> input means for inputting member information, memory means for storing said input information, detector means for detecting in a broadcast transmission at least one instruction,

<p>signal and at least one control signal; detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission; passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor; <u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; <u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>processor means operatively connected to said memory means and said detector means for processing said input information in accordance with said instruction and assembling output records that include additional information besides said input information, and recorder means for storing said output records on a memory medium.</p>
--	---

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 5,233,654, Claim 59
<p>110. <u>A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</u> <u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said</u></p>	<p>59. A receiver station system for processing and recording information of a member of a broadcast program audience for at least one remote data collection station comprising input means for inputting member information, memory means for storing said input information, detector means for detecting in a broadcast transmission at least one instruction, processor means operatively connected to said memory means and said detector means for processing said input information in accordance with said instruction and assembling output records that include additional information besides said input information, and recorder means for storing said output records on a memory medium.</p>

<p><u>at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u> transferring said at least said first discrete signal to at least one transmitter; receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	
---	--

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 5,233,654, Claim 59
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u> <u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u> receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction; transferring said at least one control signal to said at</p>	<p>59. A receiver station system for processing and recording information of a member of a broadcast program audience for at least one remote data collection station comprising input means for inputting member information, memory means for storing said input information, detector means for detecting in a broadcast transmission at least one instruction, processor means operatively connected to said memory means and said detector means for processing said input information in accordance with said instruction and assembling output records that include additional information besides said input information, and recorder means for storing said output records on a memory medium.</p>

least one origination transmitter before a specific time; and transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.	
--	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 5,233,654, Claim 59
<p>123. <u>A method of delivering a video presentation</u> at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p>transferring said at least one instruct signal to at least one transmitter;</p> <p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to</u></p>	<p>59. A receiver station system for processing and recording information of a member of a broadcast program audience for at least one remote data collection station comprising</p> <p>input means for inputting member information, memory means for storing said input information, detector means for detecting in a broadcast transmission at least one instruction, processor means operatively connected to said memory means and said detector means for processing said input information in accordance with said instruction and assembling output records that include additional information besides said input information, and</p> <p>recorder means for storing said output records on a memory medium.</p>

<p>be effective at said at least one of said plurality of receiver stations; and</p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	
---	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 5,233,654, Claim 59
<p>142. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>59. A receiver station system for processing and recording information of a member of a broadcast program audience for at least one remote data collection station comprising</p> <p>input means for inputting member information,</p> <p>memory means for storing said input information,</p> <p>detector means for detecting in a broadcast transmission at least one instruction,</p> <p>processor means operatively connected to said memory means and said detector means for processing said input information in accordance with said instruction and assembling output records that include additional information besides said input information; and</p> <p>recorder means for storing said output records on a memory medium.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 5,233,654, Claim 59
<p>143. <u>A method of outputting a video presentation</u> at a receiver station including:</p> <ul style="list-style-type: none"> receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to <u>processor instructions comprising said organized information,</u> based on said step of organizing; generating a signal based on said processor instructions; and outputting at least a portion of said video presentation based on said generated signal. 	<p>59. A receiver station system for processing and recording information of a member of a broadcast program audience for at least one remote data collection station comprising</p> <ul style="list-style-type: none"> input means for inputting member information, memory means for storing said input information, detector means for detecting in a broadcast transmission at least one instruction, processor means operatively connected to said memory means and said detector means for processing said input information in accordance with said instruction and assembling output records that include additional information besides said input information, and recorder means for storing said output records on a memory medium.

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 5,233,654, Claim 59
<p>152. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process <u>downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation</u> and have a target processor to process data, <u>said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station,</u> said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions; transferring said downloadable processor 	<p>59. A receiver station system for processing and recording information of a member of a broadcast program audience for at least one remote data collection station comprising</p> <ul style="list-style-type: none"> input means for inputting member information, memory means for storing said input information, detector means for detecting in a broadcast transmission at least one instruction, processor means operatively connected to said memory means and said detector means for processing said input information in accordance with said instruction and assembling output records that include additional information besides said input information, and recorder means for storing said output records on a memory medium.

<p>instructions to a transmitter; <u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u> transferring said one or more control signals to said transmitter; and transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	
--	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 5,233,654, Claim 59
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u> receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station; <u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u> receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>59. A receiver station system for processing and recording information of a member of a broadcast program audience for at least one remote data collection station comprising input means for inputting member information, memory means for storing said input information, detector means for detecting in a broadcast transmission at least one instruction, processor means operatively connected to said memory means and said detector means for processing said input information in accordance with said instruction and assembling output records that include additional information besides said input information, and recorder means for storing said output records on a memory medium.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 5,233,654, Claim 59
<p>162. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals</u>, said method comprising the steps of:</u></p> <p style="padding-left: 40px;">receiving a video image at a transmitter station; delivering said video image to a transmitter; <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u></p> <p style="padding-left: 40px;">transferring said at least said first of said plurality of discrete signals to said transmitter; and transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>59. A receiver station system for processing and recording information of a member of a broadcast program audience for at least one remote data collection station comprising</p> <p style="padding-left: 40px;">input means for inputting member information, memory means for storing said input information, detector means for detecting in a broadcast transmission at least one instruction, processor means operatively connected to said memory means and said detector means for processing said input information in accordance with said instruction and assembling output records that include additional information besides said input information, and recorder means for storing said output records on a memory medium.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus.

Application Claim 167	U.S. Pat. No. 5,233,654, Claim 59
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u></p> <p style="padding-left: 40px;">receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-</p>	<p>59. A receiver station system for processing and recording information of a member of a broadcast program audience for at least one remote data collection station comprising</p> <p style="padding-left: 40px;">input means for inputting member information,</p>

<p>screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</p> <p>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal of said downloadable code;</p> <p>passing said at least a first discrete signal of said downloadable code to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u></p> <p><u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u></p> <p>wherein said method delivers said video graphic presentation.</p>	<p>memory means for storing said input information,</p> <p>detector means for detecting in a broadcast transmission at least one instruction,</p> <p>processor means operatively connected to said memory means and said detector means for processing said input information in accordance with said instruction and assembling output records that include additional information besides said input information, and</p> <p>recorder means for storing said output records on a memory medium.</p>
--	---

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 5,233,654, Claim 59
<p>171. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is</p>	<p>59. A receiver station system for processing and recording information of a member of a broadcast program audience for at least one remote data collection station comprising</p> <p>input means for inputting member information,</p> <p>memory means for storing said input information,</p> <p>detector means for detecting in a broadcast</p>

programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image,
said method comprising the steps of:

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;

transferring said at least one discrete signal to a transmitter;

receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said at least one discrete signal and said one or more control signals,

wherein said method delivers said video graphic presentation.

transmission at least one instruction,

processor means operatively connected to said memory means and said detector means for processing said input information in accordance with said instruction and assembling output records that include additional information besides said input information, and

recorder means for storing said output records on a memory medium.

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 5,233,654, Claim 59
<p>175. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</p> <p>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>59. A receiver station system for processing and recording information of a member of a broadcast program audience for at least one remote data collection station comprising</p> <p>input means for inputting member information,</p> <p>memory means for storing said input information,</p> <p>detector means for detecting in a broadcast transmission at least one instruction,</p> <p>processor means operatively connected to said memory means and said detector means for processing said input information in accordance with said instruction and assembling output records that include additional information besides said input information, and</p> <p>recorder means for storing said output records on a memory medium.</p>

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 5,233,654, Claim 59
<p>177. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>transferring said one or more instruct signals to said transmitter; and</p> <p>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>59. A receiver station system for processing and recording information of a member of a broadcast program audience for at least one remote data collection station comprising</p> <p>input means for inputting member information,</p> <p>memory means for storing said input information,</p> <p>detector means for detecting in a broadcast transmission at least one instruction,</p> <p>processor means operatively connected to said memory means and said detector means for processing said input information in accordance with said instruction and assembling output records that include additional information besides said input information, and</p> <p>recorder means for storing said output records on a memory medium.</p>

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 5,233,654, Claim 59
<p>179. <u>A method of outputting a video graphic presentation</u> at a receiver station including:</p> <p>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</p> <p>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal;</p> <p>passing said at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image;</u> and</p> <p><u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u></p> <p>wherein said method delivers said video graphic presentation.</p>	<p>59. A receiver station system for processing and recording information of a member of a broadcast program audience for at least one remote data collection station comprising</p> <p>input means for inputting member information,</p> <p>memory means for storing said input information,</p> <p>detector means for detecting in a broadcast transmission at least one instruction,</p> <p>processor means operatively connected to said memory means and said detector means for processing said input information in accordance with said instruction and assembling output records that include additional information besides said input information, and</p> <p>recorder means for storing said output records on a memory medium.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus.

Application Claim 56	U.S. Pat. No. 5,233,654, Claim 63
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p><u>and</u></p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>63. A receiver station system for processing and recording information of a member of a broadcast program audience for at least one remote data collection station comprising</p> <p>input means for inputting member information, memory means for storing said input information, detector means for detecting in a broadcast transmission at least one datum,</p> <p>processor means operatively connected to said memory means and said detector means for processing said input information and said datum and assembling output records that include additional information besides said input information, and recorder means for storing said output records on a memory medium.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 5,233,654, Claim 63
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable</u></p>	<p>63. A receiver station system for processing and recording information of a member of a broadcast program audience for at least one remote data collection station comprising</p> <p>input means for inputting member information, memory means for storing said input information, detector means for detecting in a broadcast transmission at least one datum,</p> <p>processor means operatively connected to said memory means and said detector means for processing said input information and said datum and assembling output records that include additional information besides said input information, and recorder means for storing said output records on a memory medium.</p>

<p>processor instructions having at said at least one receiver station a target processor to process data; transferring said downloadable processor instructions to a transmitter; receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation; transferring said at least one control signal to said transmitter; and transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	
---	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 5,233,654, Claim 63
<p>80. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of: receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station; <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>63. A receiver station system for processing and recording information of a member of a broadcast program audience for at least one remote data collection station comprising input means for inputting member information, memory means for storing said input information, detector means for detecting in a broadcast transmission at least one datum, processor means operatively connected to said memory means and said detector means for processing said input information and said datum and assembling output records that include additional information besides said input information, and recorder means for storing said output records on a memory medium.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 5,233,654, Claim 63
<p>84. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, <u>wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals</u> and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving video at a transmitter station; delivering said video to a transmitter; receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video; transferring said first discrete signal to said transmitter; and transmitting said video and said first discrete signal to said at least one receiver station. 	<p>63. A receiver station system for processing and recording information of a member of a broadcast program audience for at least one remote data collection station comprising</p> <ul style="list-style-type: none"> input means for inputting member information, memory means for storing said input information, detector means for detecting in a broadcast transmission at least one datum, processor means operatively connected to said memory means and said detector means for processing said input information and said datum and assembling output records that include additional information besides said input information, and recorder means for storing said output records on a memory medium.

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 5,233,654, Claim 63
<p>93. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete 	<p>63. A receiver station system for processing and recording information of a member of a broadcast program audience for at least one remote data collection station comprising</p> <ul style="list-style-type: none"> input means for inputting member information, memory means for storing said input information, detector means for detecting in a broadcast transmission at least one datum,

<p>signal and at least one control signal; detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission; passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor; <u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; <u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>processor means operatively connected to said memory means and said detector means for processing said input information and said datum and assembling output records that include additional information besides said input information, and recorder means for storing said output records on a memory medium.</p>
--	---

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 5,233,654, Claim 63
<p>110. A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of: <u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said</u></p>	<p>63. A receiver station system for processing and recording information of a member of a broadcast program audience for at least one remote data collection station comprising input means for inputting member information, memory means for storing said input information, detector means for detecting in a broadcast transmission at least one datum, processor means operatively connected to said memory means and said detector means for processing said input information and said datum and assembling output records that include additional information besides said input information, and recorder means for storing said output records on a memory medium.</p>

<p><u>at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u> transferring said at least said first discrete signal to at least one transmitter; <u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u> transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	
--	--

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 5,233,654, Claim 63
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction,</u> said method comprising the steps of: <u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u> receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction; transferring said at least one control signal to said at</p>	<p>63. A receiver station system for processing and recording information of a member of a broadcast program audience for at least one remote data collection station comprising input means for inputting member information, memory means for storing said input information, detector means for detecting in a broadcast transmission at least one datum, processor means operatively connected to said memory means and said detector means for processing said input information and said datum and assembling output records that include additional information besides said input information, and recorder means for storing said output records on a memory medium.</p>

<p>least one origination transmitter before a specific time; and transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	
---	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 5,233,654, Claim 63
<p>123. <u>A method of delivering a video presentation</u> at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</p> <p><u>receiving at at least one of said first remote</u> <u>transmitter station and a second remote transmitter</u> <u>station at least one instruct signal which is effective at</u> <u>a particular receiver station of said plurality of receiver</u> <u>stations to generate locally and output said second</u> <u>image of said video presentation for delivery in</u> <u>conjunction with said first image;</u></p> <p>transferring said at least one instruct signal to at least one transmitter;</p> <p><u>receiving at least one first discrete signal and at least</u> <u>one control signal at said at least one of said first</u> <u>remote transmitter station and said second remote</u> <u>transmitter station, said at least one first discrete signal</u> <u>including only partial information of said one of a</u> <u>code and an identifier and said at least one control</u> <u>signal operative to provide said one of a code and an</u> <u>identifier and designate at said at least one of said</u> <u>plurality of receiver stations by organizing said partial</u> <u>information with information contained in a second</u> <u>discrete signal at said at least one of said plurality of</u> <u>receiver stations,</u> wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to</p>	<p>63. A receiver station system for processing and recording information of a member of a broadcast program audience for at least one remote data collection station comprising</p> <p>input means for inputting member information, memory means for storing said input information, detector means for detecting in a broadcast transmission at least one datum, processor means operatively connected to said memory means and said detector means for processing said input information and said datum and assembling output records that include additional information besides said input information, and recorder means for storing said output records on a memory medium.</p>

<p>be effective at said at least one of said plurality of receiver stations; and</p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	
---	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 5,233,654, Claim 63
<p>142. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction;</u> and</p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>63. A receiver station system for processing and recording information of a member of a broadcast program audience for at least one remote data collection station comprising</p> <p>input means for inputting member information, memory means for storing said input information, detector means for detecting in a broadcast transmission at least one datum,</p> <p>processor means operatively connected to said memory means and said detector means for processing said input information and said datum and assembling output records that include additional information besides said input information, and recorder means for storing said output records on a memory medium.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 5,233,654, Claim 63
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u> receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to <u>processor instructions comprising said organized information,</u> based on said step of organizing; generating a signal based on said processor instructions; and outputting at least a portion of said video presentation based on said generated signal.</p>	<p>63. A receiver station system for processing and recording information of a member of a broadcast program audience for at least one remote data collection station comprising input means for inputting member information, memory means for storing said input information, detector means for detecting in a broadcast transmission at least one datum, processor means operatively connected to said memory means and said detector means for processing said input information and said datum and assembling output records that include additional information besides said input information, and recorder means for storing said output records on a memory medium.</p>

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 5,233,654, Claim 63
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station,</u> said method comprising the steps of: receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions; transferring said downloadable processor</p>	<p>63. A receiver station system for processing and recording information of a member of a broadcast program audience for at least one remote data collection station comprising input means for inputting member information, memory means for storing said input information, detector means for detecting in a broadcast transmission at least one datum, processor means operatively connected to said memory means and said detector means for processing said input information and said datum and assembling output records that include additional information besides said input information, and recorder means for storing said output records on a memory medium.</p>

<p>instructions to a transmitter; <u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u> transferring said one or more control signals to said transmitter; and transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	
--	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 5,233,654, Claim 63
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u> receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station; <u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u> receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>63. A receiver station system for processing and recording information of a member of a broadcast program audience for at least one remote data collection station comprising input means for inputting member information, memory means for storing said input information, detector means for detecting in a broadcast transmission at least one datum, processor means operatively connected to said memory means and said detector means for processing said input information and said datum and assembling output records that include additional information besides said input information, and recorder means for storing said output records on a memory medium.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 5,233,654, Claim 63
<p>162. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals</u>, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving a video image at a transmitter station; delivering said video image to a transmitter; <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> transferring said at least said first of said plurality of discrete signals to said transmitter; and transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station. 	<p>63. A receiver station system for processing and recording information of a member of a broadcast program audience for at least one remote data collection station comprising</p> <ul style="list-style-type: none"> input means for inputting member information, memory means for storing said input information, detector means for detecting in a broadcast transmission at least one datum, processor means operatively connected to said memory means and said detector means for processing said input information and said datum and assembling output records that include additional information besides said input information, and recorder means for storing said output records on a memory medium.

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus.

Application Claim 167	U.S. Pat. No. 5,233,654, Claim 63
<p>167. <u>A method of outputting a video graphic presentation</u> at a receiver station including:</p> <ul style="list-style-type: none"> receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full- 	<p>63. A receiver station system for processing and recording information of a member of a broadcast program audience for at least one remote data collection station comprising</p> <ul style="list-style-type: none"> input means for inputting member information,

<p>screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</p> <p>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal of said downloadable code;</p> <p>passing said at least a first discrete signal of said downloadable code to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u></p> <p><u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u></p> <p>wherein said method delivers said video graphic presentation.</p>	<p>memory means for storing said input information, detector means for detecting in a broadcast transmission at least one datum,</p> <p>processor means operatively connected to said memory means and said detector means for processing said input information and said datum and assembling output records that include additional information besides said input information, and</p> <p>recorder means for storing said output records on a memory medium.</p>
--	---

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 5,233,654, Claim 63
<p>171. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is</p>	<p>63. A receiver station system for processing and recording information of a member of a broadcast program audience for at least one remote data collection station comprising</p> <p>input means for inputting member information, memory means for storing said input information, detector means for detecting in a broadcast</p>

programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;

transferring said at least one discrete signal to a transmitter;

receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said at least one discrete signal and said one or more control signals,

wherein said method delivers said video graphic presentation.

transmission at least one datum,

processor means operatively connected to said memory means and said detector means for processing said input information and said datum and assembling output records that include additional information besides said input information, and recorder means for storing said output records on a memory medium.

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 5,233,654, Claim 63
<p>175. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</p> <p>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>63. A receiver station system for processing and recording information of a member of a broadcast program audience for at least one remote data collection station comprising</p> <p>input means for inputting member information, memory means for storing said input information, detector means for detecting in a broadcast transmission at least one datum,</p> <p>processor means operatively connected to said memory means and said detector means for processing said input information and said datum and assembling output records that include additional information besides said input information, and recorder means for storing said output records on a memory medium.</p>

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 5,233,654, Claim 63
<p>177. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>transferring said one or more instruct signals to said transmitter; and</p> <p>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>63. A receiver station system for processing and recording information of a member of a broadcast program audience for at least one remote data collection station comprising</p> <p>input means for inputting member information,</p> <p>memory means for storing said input information,</p> <p>detector means for detecting in a broadcast transmission at least one datum,</p> <p>processor means operatively connected to said memory means and said detector means for processing said input information and said datum and assembling output records that include additional information besides said input information, and</p> <p>recorder means for storing said output records on a memory medium.</p>

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 5,233,654, Claim 63
<p>179. <u>A method of outputting a video graphic presentation</u> at a receiver station including:</p> <p>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</p> <p>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal;</p> <p>passing said at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u></p> <p><u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u></p> <p>wherein said method delivers said video graphic presentation.</p>	<p>63. A receiver station system for processing and recording information of a member of a broadcast program audience for at least one remote data collection station comprising</p> <p>input means for inputting member information,</p> <p>memory means for storing said input information,</p> <p>detector means for detecting in a broadcast transmission at least one datum,</p> <p>processor means operatively connected to said memory means and said detector means for processing said input information and said datum and assembling output records that include additional information besides said input information, and</p> <p>recorder means for storing said output records on a memory medium.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus.

Application Claim 56	U.S. Pat. No. 5,233,654, Claim 67
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p>and</p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>67. A receiver station system for processing, recording, and transferring information of a member of a broadcast program audience and transferring output to at least one remote data collection station comprising</p> <p>input means for inputting member information,</p> <p>first memory means for storing said input information,</p> <p>detector means for detecting in a broadcast transmission at least one datum,</p> <p>first processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and assembling output records that include additional information besides said input information,</p> <p>recorder means for storing said output records,</p> <p>transmission means for transmitting output of said recorder means to said data collection station,</p> <p>second detector means for detecting in a broadcast transmission at least one instruction, and</p> <p>second processor means operatively connected to said transmission means and said second detector means for causing said transmission means to transmit at least some of the output of said recorder means in response to said instruction.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 5,233,654, Claim 67
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable</u></p>	<p>67. A receiver station system for processing, recording, and transferring information of a member of a broadcast program audience and transferring output to at least one remote data collection station comprising</p> <p>input means for inputting member information,</p> <p>first memory means for storing said input information,</p> <p>detector means for detecting in a broadcast transmission at least one datum,</p> <p>first processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and assembling output records that include additional information besides said input information,</p> <p>recorder means for storing said output records,</p> <p>transmission means for transmitting output of said</p>

<p><u>processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</u> transferring said downloadable processor instructions to a transmitter; receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation; transferring said at least one control signal to said transmitter; and transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	<p>recorder means to said data collection station, second detector means for detecting in a broadcast transmission at least one instruction, and second processor means operatively connected to said transmission means and said second detector means for causing said transmission means to transmit at least some of the output of said recorder means in response to said instruction.</p>
---	---

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 5,233,654, Claim 67
<p>80. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of: receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station; <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</p>	<p>67. A receiver station system for processing, recording, and transferring information of a member of a broadcast program audience and transferring output to at least one remote data collection station comprising input means for inputting member information, first memory means for storing said input information, detector means for detecting in a broadcast transmission at least one datum, first processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and assembling output records that include additional information besides said input information, recorder means for storing said output records, transmission means for transmitting output of said recorder means to said data collection station, second detector means for detecting in a broadcast transmission at least one instruction, and second processor means operatively connected to said transmission means and said second detector means for causing said transmission means to</p>

transmitting said at least one control signal from said origination transmitter before a specific time.	transmit at least some of the output of said recorder means in response to said instruction.
---	--

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 5,233,654, Claim 67
<p>84. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, <u>wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals</u> and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving video at a transmitter station; delivering said video to a transmitter; <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and transmitting said video and said first discrete signal to said at least one receiver station. 	<p>67. A receiver station system for processing, recording, and transferring information of a member of a broadcast program audience and transferring output to at least one remote data collection station comprising</p> <ul style="list-style-type: none"> input means for inputting member information, first memory means for storing said input information, detector means for detecting in a broadcast transmission at least one datum, first processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and assembling output records that include additional information besides said input information, recorder means for storing said output records, transmission means for transmitting output of said recorder means to said data collection station, second detector means for detecting in a broadcast transmission at least one instruction, and second processor means operatively connected to said transmission means and said second detector means for causing said transmission means to transmit at least some of the output of said recorder means in response to said instruction.

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 5,233,654, Claim 67
<p>93. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said</p>	<p>67. A receiver station system for processing, recording, and transferring information of a member of a broadcast program audience and transferring output to at least one remote data collection station</p>

<p>method comprising the steps of:</p> <p>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal;</p> <p>detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission;</p> <p>passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor;</p> <p><u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>comprising</p> <p>input means for inputting member information, first memory means for storing said input information,</p> <p>detector means for detecting in a broadcast transmission at least one datum,</p> <p>first processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and assembling output records that include additional information besides said input information,</p> <p>recorder means for storing said output records, transmission means for transmitting output of said recorder means to said data collection station,</p> <p>second detector means for detecting in a broadcast transmission at least one instruction, and</p> <p>second processor means operatively connected to said transmission means and said second detector means for causing said transmission means to transmit at least some of the output of said recorder means in response to said instruction.</p>
---	---

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 5,233,654, Claim 67
<p>110. A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</p> <p><u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information</u></p>	<p>67. A receiver station system for processing, recording, and transferring information of a member of a broadcast program audience and transferring output to at least one remote data collection station comprising</p> <p>input means for inputting member information, first memory means for storing said input information,</p> <p>detector means for detecting in a broadcast transmission at least one datum,</p> <p>first processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and</p>

<p><u>contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u></p> <p>transferring said at least said first discrete signal to at least one transmitter;</p> <p><u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u></p> <p>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>assembling output records that include additional information besides said input information,</p> <p>recorder means for storing said output records,</p> <p>transmission means for transmitting output of said recorder means to said data collection station,</p> <p>second detector means for detecting in a broadcast transmission at least one instruction, and</p> <p>second processor means operatively connected to said transmission means and said second detector means for causing said transmission means to transmit at least some of the output of said recorder means in response to said instruction.</p>
---	--

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 5,233,654, Claim 67
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u></p> <p><u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u></p> <p>receiving at least one control signal which at said</p>	<p>67. A receiver station system for processing, recording, and transferring information of a member of a broadcast program audience and transferring output to at least one remote data collection station comprising</p> <p>input means for inputting member information,</p> <p>first memory means for storing said input information,</p> <p>detector means for detecting in a broadcast transmission at least one datum,</p> <p>first processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and assembling output records that include additional information besides said input information,</p> <p>recorder means for storing said output records,</p> <p>transmission means for transmitting output of said recorder means to said data collection station,</p> <p>second detector means for detecting in a broadcast transmission at least one instruction, and</p> <p>second processor means operatively connected to said transmission means and said second detector means for causing said transmission means to transmit at least some of the output of said recorder</p>

remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction; transferring said at least one control signal to said at least one origination transmitter before a specific time; and transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.	means in response to said instruction.
---	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 5,233,654, Claim 67
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u></p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p>transferring said at least one instruct signal to at least one transmitter;</p> <p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of</u></p>	<p>67. A receiver station system for processing, recording, and transferring information of a member of a broadcast program audience and transferring output to at least one remote data collection station comprising</p> <p>input means for inputting member information,</p> <p>first memory means for storing said input information,</p> <p>detector means for detecting in a broadcast transmission at least one datum,</p> <p>first processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and assembling output records that include additional information besides said input information,</p> <p>recorder means for storing said output records,</p> <p>transmission means for transmitting output of said recorder means to said data collection station,</p> <p>second detector means for detecting in a broadcast transmission at least one instruction, and</p> <p>second processor means operatively connected to said transmission means and said second detector means for causing said transmission means to transmit at least some of the output of said recorder means in response to said instruction.</p>

<p><u>receiver stations</u>, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and</p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	
--	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 5,233,654, Claim 67
<p>142. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>67. A receiver station system for processing, recording, and transferring information of a member of a broadcast program audience and transferring output to at least one remote data collection station comprising</p> <p>input means for inputting member information,</p> <p>first memory means for storing said input information,</p> <p>detector means for detecting in a broadcast transmission at least one datum,</p> <p>first processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and assembling output records that include additional information besides said input information,</p> <p>recorder means for storing said output records,</p> <p>transmission means for transmitting output of said recorder means to said data collection station,</p> <p>second detector means for detecting in a broadcast transmission at least one instruction, and</p> <p>second processor means operatively connected to said transmission means and said second detector means for causing said transmission means to transmit at least some of the output of said recorder means in response to said instruction.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 5,233,654, Claim 67
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u> receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to <u>processor instructions comprising said organized information,</u> based on said step of organizing; generating a signal based on said processor instructions; and outputting at least a portion of said video presentation based on said generated signal.</p>	<p>67. A receiver station system for processing, recording, and transferring information of a member of a broadcast program audience and transferring output to at least one remote data collection station comprising input means for inputting member information, first memory means for storing said input information, detector means for detecting in a broadcast transmission at least one datum, first processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and assembling output records that include additional information besides said input information, recorder means for storing said output records, transmission means for transmitting output of said recorder means to said data collection station, second detector means for detecting in a broadcast transmission at least one instruction, and second processor means operatively connected to said transmission means and said second detector means for causing said transmission means to transmit at least some of the output of said recorder means in response to said instruction.</p>

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 5,233,654, Claim 67
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video</u></p>	<p>67. A receiver station system for processing, recording, and transferring information of a member of a broadcast program audience and transferring output to at least one remote data collection station comprising input means for inputting member information, first memory means for storing said input information, detector means for detecting in a broadcast transmission at least one datum, first processor means operatively connected to said</p>

<p><u>presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</u></p> <ul style="list-style-type: none"> receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions; transferring said downloadable processor instructions to a transmitter; <u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u> transferring said one or more control signals to said transmitter; and transmitting a transmission comprising said downloadable processor instructions and said one or more control signals. 	<p>first memory means and said detector means for processing said input information and said datum and assembling output records that include additional information besides said input information,</p> <p>recorder means for storing said output records,</p> <p>transmission means for transmitting output of said recorder means to said data collection station,</p> <p>second detector means for detecting in a broadcast transmission at least one instruction, and</p> <p>second processor means operatively connected to said transmission means and said second detector means for causing said transmission means to transmit at least some of the output of said recorder means in response to said instruction.</p>
--	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 5,233,654, Claim 67
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <ul style="list-style-type: none"> receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station; <u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u> 	<p>67. A receiver station system for processing, recording, and transferring information of a member of a broadcast program audience and transferring output to at least one remote data collection station comprising</p> <ul style="list-style-type: none"> input means for inputting member information, first memory means for storing said input information, detector means for detecting in a broadcast transmission at least one datum, first processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and assembling output records that include additional information besides said input information, recorder means for storing said output records,

<p>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</p> <p>transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>transmission means for transmitting output of said recorder means to said data collection station,</p> <p>second detector means for detecting in a broadcast transmission at least one instruction, and</p> <p>second processor means operatively connected to said transmission means and said second detector means for causing said transmission means to transmit at least some of the output of said recorder means in response to said instruction.</p>
---	--

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 5,233,654, Claim 67
<p>162. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals</u>, said method comprising the steps of:</u></p> <p>receiving a video image at a transmitter station;</p> <p>delivering said video image to a transmitter;</p> <p><u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u></p> <p>transferring said at least said first of said plurality of discrete signals to said transmitter; and</p> <p>transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>67. A receiver station system for processing, recording, and transferring information of a member of a broadcast program audience and transferring output to at least one remote data collection station comprising</p> <p>input means for inputting member information,</p> <p>first memory means for storing said input information,</p> <p>detector means for detecting in a broadcast transmission at least one datum,</p> <p>first processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and assembling output records that include additional information besides said input information,</p> <p>recorder means for storing said output records,</p> <p>transmission means for transmitting output of said recorder means to said data collection station,</p> <p>second detector means for detecting in a broadcast transmission at least one instruction, and</p> <p>second processor means operatively connected to said transmission means and said second detector means for causing said transmission means to transmit at least some of the output of said recorder means in response to said instruction.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus.

Application Claim 167	U.S. Pat. No. 5,233,654, Claim 67
<p>167. <u>A method of outputting a video graphic presentation</u> at a receiver station including:</p> <p>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</p> <p>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal of said downloadable code;</p> <p>passing said at least a first discrete signal of said downloadable code to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u></p> <p><u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u></p> <p>wherein said method delivers said video graphic presentation.</p>	<p>67. A receiver station system for processing, recording, and transferring information of a member of a broadcast program audience and transferring output to at least one remote data collection station comprising</p> <p>input means for inputting member information,</p> <p>first memory means for storing said input information,</p> <p>detector means for detecting in a broadcast transmission at least one datum,</p> <p>first processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and assembling output records that include additional information besides said input information,</p> <p>recorder means for storing said output records,</p> <p>transmission means for transmitting output of said recorder means to said data collection station,</p> <p>second detector means for detecting in a broadcast transmission at least one instruction, and</p> <p>second processor means operatively connected to said transmission means and said second detector means for causing said transmission means to transmit at least some of the output of said recorder means in response to said instruction.</p>

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 5,233,654, Claim 67
<p>171. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, <u>wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image,</u> said method comprising the steps of:</p> <p style="padding-left: 2em;"><u>receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</u></p> <p style="padding-left: 2em;">transferring said at least one discrete signal to a transmitter;</p> <p style="padding-left: 2em;"><u>receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;</u></p> <p style="padding-left: 2em;">transferring said one or more control signals to said transmitter; and</p> <p style="padding-left: 2em;">transmitting a transmission comprising said at least one discrete signal and said one or more control signals,</p>	<p>67. A receiver station system for processing, recording, and transferring information of a member of a broadcast program audience and transferring output to at least one remote data collection station comprising</p> <p style="padding-left: 2em;">input means for inputting member information,</p> <p style="padding-left: 2em;">first memory means for storing said input information,</p> <p style="padding-left: 2em;">detector means for detecting in a broadcast transmission at least one datum,</p> <p style="padding-left: 2em;">first processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and assembling output records that include additional information besides said input information,</p> <p style="padding-left: 2em;">recorder means for storing said output records,</p> <p style="padding-left: 2em;">transmission means for transmitting output of said recorder means to said data collection station,</p> <p style="padding-left: 2em;">second detector means for detecting in a broadcast transmission at least one instruction, and</p> <p style="padding-left: 2em;">second processor means operatively connected to said transmission means and said second detector means for causing said transmission means to transmit at least some of the output of said recorder means in response to said instruction.</p>

wherein said method delivers said video graphic presentation.	
---	--

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 5,233,654, Claim 67
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u></p> <p style="padding-left: 20px;">receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</p> <p style="padding-left: 20px;"><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p style="padding-left: 20px;">receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</p> <p style="padding-left: 20px;">transmitting a transmission that contains said at</p>	<p>67. A receiver station system for processing, recording, and transferring information of a member of a broadcast program audience and transferring output to at least one remote data collection station comprising</p> <p style="padding-left: 20px;">input means for inputting member information, first memory means for storing said input information,</p> <p style="padding-left: 20px;">detector means for detecting in a broadcast transmission at least one datum,</p> <p style="padding-left: 20px;">first processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and assembling output records that include additional information besides said input information,</p> <p style="padding-left: 20px;">recorder means for storing said output records, transmission means for transmitting output of said recorder means to said data collection station,</p> <p style="padding-left: 20px;">second detector means for detecting in a broadcast transmission at least one instruction, and</p> <p style="padding-left: 20px;">second processor means operatively connected to said transmission means and said second detector means for causing said transmission means to transmit at least some of the output of said recorder means in response to said instruction.</p>

<p>least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time, wherein said method delivers said video graphic presentation.</p>	
---	--

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 5,233,654, Claim 67
<p>177. A method of <u>delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>transferring said one or more instruct signals to said transmitter; and</p> <p>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one</p>	<p>67. A receiver station system for processing, recording, and transferring information of a member of a broadcast program audience and transferring output to at least one remote data collection station comprising</p> <p>input means for inputting member information,</p> <p>first memory means for storing said input information,</p> <p>detector means for detecting in a broadcast transmission at least one datum,</p> <p>first processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and assembling output records that include additional information besides said input information,</p> <p>recorder means for storing said output records,</p> <p>transmission means for transmitting output of said recorder means to said data collection station,</p> <p>second detector means for detecting in a broadcast transmission at least one instruction, and</p> <p>second processor means operatively connected to said transmission means and said second detector means for causing said transmission means to transmit at least some of the output of said recorder means in response to said instruction.</p>

receiver station, wherein said method delivers said video graphic presentation.	
--	--

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 5,233,654, Claim 67
<p>179. <u>A method of outputting a video graphic presentation</u> at a receiver station including:</p> <ul style="list-style-type: none"> receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image; passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen; displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen; detecting said at least a first discrete signal; passing said at least a first discrete signal to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image;</u> and <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image;</u> <p>wherein said method delivers said video graphic presentation.</p>	<p>67. A receiver station system for processing, recording, and transferring information of a member of a broadcast program audience and transferring output to at least one remote data collection station comprising</p> <ul style="list-style-type: none"> input means for inputting member information, first memory means for storing said input information, detector means for detecting in a broadcast transmission at least one datum, first processor means operatively connected to said first memory means and said detector means for processing said input information and said datum and assembling output records that include additional information besides said input information, recorder means for storing said output records, transmission means for transmitting output of said recorder means to said data collection station, second detector means for detecting in a broadcast transmission at least one instruction, and second processor means operatively connected to said transmission means and said second detector means for causing said transmission means to transmit at least some of the output of said recorder means in response to said instruction.

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus.

Application Claim 56	U.S. Pat. No. 5,335,277, Claim 1
<p>56. A method for receiving and processing data for use with an interactive video apparatus, <u>said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source</u>, said method comprising the steps of:</p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p>communicating one of said at least said first request and a second request to a remote data source;</p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p>and</p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>1. A method of processing control signals and controlling equipment at a remote site based on broadcast transmissions including:</p> <p>(a) the step of receiving at said remote site a broadcast carrier transmission;</p> <p>(b) the step of demodulating said broadcast carrier transmission to detect an information transmission therein;</p> <p>(c) the step of detecting and identifying at said remote site control signals associated with said information transmission;</p> <p>(d) the step of passing at least a portion of said control signals to a computer control means at said remote site;</p> <p>(e) the step of said computer control means determining based on instructions included in said control signals whether receiver means at said remote site is operating; and</p> <p>(f) the step of directing, based on the result of said determination step, said information transmission and a selected portion of said control signals to (1) said receiver means and associated computer equipment or (2) a recorder means activated by said computer control means.</p>

Application Claim 75	U.S. Pat. No. 5,335,277, Claim 1
<p>75. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, <u>said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image</u>, said method comprising the steps of:</p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable</u></p>	<p>1. A method of processing control signals and controlling equipment at a remote site based on broadcast transmissions including:</p> <p>(a) the step of receiving at said remote site a broadcast carrier transmission;</p> <p>(b) the step of demodulating said broadcast carrier transmission to detect an information transmission therein;</p> <p>(c) the step of detecting and identifying at said remote site control signals associated with said information transmission;</p> <p>(d) the step of passing at least a portion of said control signals to a computer control means at said remote site;</p> <p>(e) the step of said computer control means determining based on instructions included in said control signals whether receiver means at said remote site is operating; and</p> <p>(f) the step of directing, based on the result of said determination step, said information transmission and a selected portion of said control signals to (1) said</p>

<p>processor instructions having at said at least one receiver station a target processor to process data; transferring said downloadable processor instructions to a transmitter; receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation; transferring said at least one control signal to said transmitter; and transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	<p>receiver means and associated computer equipment or (2) a recorder means activated by said computer control means.</p>
---	---

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 80	U.S. Pat. No. 5,335,277, Claim 1
<p>80. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of: receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station; <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>1. A method of processing control signals and controlling equipment at a remote site based on broadcast transmissions including: (a) the step of receiving at said remote site a broadcast carrier transmission; (b) the step of demodulating said broadcast carrier transmission to detect an information transmission therein; (c) the step of detecting and identifying at said remote site control signals associated with said information transmission; (d) the step of passing at least a portion of said control signals to a computer control means at said remote site; (e) the step of said computer control means determining based on instructions included in said control signals whether receiver means at said remote site is operating; and (f) the step of directing, based on the result of said determination step, said information transmission and a selected portion of said control signals to (1) said receiver means and associated computer equipment or (2) a recorder means activated by said computer control means.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 84	U.S. Pat. No. 5,335,277, Claim 1
<p>84. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, <u>wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals</u> and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving video at a transmitter station; delivering said video to a transmitter; <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and transmitting said video and said first discrete signal to said at least one receiver station. 	<p>1. A method of processing control signals and controlling equipment at a remote site based on broadcast transmissions including:</p> <ul style="list-style-type: none"> (a) the step of receiving at said remote site a broadcast carrier transmission; (b) the step of demodulating said broadcast carrier transmission to detect an information transmission therein; (c) the step of detecting and identifying at said remote site control signals associated with said information transmission; (d) the step of passing at least a portion of said control signals to a computer control means at said remote site; (e) the step of said computer control means determining based on instructions included in said control signals whether receiver means at said remote site is operating; and (f) the step of directing, based on the result of said determination step, said information transmission and a selected portion of said control signals to (1) said receiver means and associated computer equipment or (2) a recorder means activated by said computer control means.

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 93	U.S. Pat. No. 5,335,277, Claim 1
<p>93. A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving at least one information transmission at 	<p>1. A method of processing control signals and controlling equipment at a remote site based on broadcast transmissions including:</p> <ul style="list-style-type: none"> (a) the step of receiving at said remote site a broadcast carrier transmission; (b) the step of demodulating said broadcast carrier

<p>said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal; detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission; passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor; <u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; <u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>transmission to detect an information transmission therein; (c) the step of detecting and identifying at said remote site control signals associated with said information transmission; (d) the step of passing at least a portion of said control signals to a computer control means at said remote site; (e) the step of said computer control means determining based on instructions included in said control signals whether receiver means at said remote site is operating; and (f) the step of directing, based on the result of said determination step, said information transmission and a selected portion of said control signals to (1) said receiver means and associated computer equipment or (2) a recorder means activated by said computer control means.</p>
---	--

Application Claim 110	U.S. Pat. No. 5,335,277, Claim 1
<p>110. A method of <u>outputting a video presentation</u> at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of: <u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target</u></p>	<p>1. A method of processing control signals and controlling equipment at a remote site based on broadcast transmissions including: (a) the step of receiving at said remote site a broadcast carrier transmission; (b) the step of demodulating said broadcast carrier transmission to detect an information transmission therein; (c) the step of detecting and identifying at said remote site control signals associated with said information transmission; (d) the step of passing at least a portion of said control signals to a computer control means at said remote site; (e) the step of said computer control means determining based on instructions included in said control signals whether receiver means at said remote site is operating; and (f) the step of directing, based on the result of said</p>

<p>processor to process data; transferring said at least said first discrete signal to at least one transmitter; <u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u> transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>determination step, said information transmission and a selected portion of said control signals to (1) said receiver means and associated computer equipment or (2) a recorder means activated by said computer control means.</p>
--	--

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 116	U.S. Pat. No. 5,335,277, Claim 1
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u> <u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u> receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction; transferring said at least one control signal to said at least one origination transmitter before a specific time;</p>	<p>1. A method of processing control signals and controlling equipment at a remote site based on broadcast transmissions including: (a) the step of receiving at said remote site a broadcast carrier transmission; (b) the step of demodulating said broadcast carrier transmission to detect an information transmission therein; (c) the step of detecting and identifying at said remote site control signals associated with said information transmission; (d) the step of passing at least a portion of said control signals to a computer control means at said remote site; (e) the step of said computer control means determining based on instructions included in said control signals whether receiver means at said remote site is operating; and (f) the step of directing, based on the result of said determination step, said information transmission and a selected portion of said control signals to (1) said receiver means and associated computer equipment or (2) a recorder means activated by said computer control means.</p>

and transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.	
---	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 123	U.S. Pat. No. 5,335,277, Claim 1
<p>123. <u>A method of delivering a video presentation at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u></p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p>transferring said at least one instruct signal to at least one transmitter;</p> <p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of</u></p>	<p>1. A method of processing control signals and controlling equipment at a remote site based on broadcast transmissions including:</p> <p>(a) the step of receiving at said remote site a broadcast carrier transmission;</p> <p>(b) the step of demodulating said broadcast carrier transmission to detect an information transmission therein;</p> <p>(c) the step of detecting and identifying at said remote site control signals associated with said information transmission;</p> <p>(d) the step of passing at least a portion of said control signals to a computer control means at said remote site;</p> <p>(e) the step of said computer control means determining based on instructions included in said control signals whether receiver means at said remote site is operating; and</p> <p>(f) the step of directing, based on the result of said determination step, said information transmission and a selected portion of said control signals to (1) said receiver means and associated computer equipment or (2) a recorder means activated by said computer control means.</p>

<p><u>receiver stations; and</u> transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	
--	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 142	U.S. Pat. No. 5,335,277, Claim 1
<p>142. A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of: receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal; detecting said at least a first discrete signal and said at least one control signal in said information transmission; passing said detected at least a first discrete signal to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; <u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>1. A method of processing control signals and controlling equipment at a remote site based on broadcast transmissions including: (a) the step of receiving at said remote site a broadcast carrier transmission; (b) the step of demodulating said broadcast carrier transmission to detect an information transmission therein; (c) the step of detecting and identifying at said remote site control signals associated with said information transmission; (d) the step of passing at least a portion of said control signals to a computer control means at said remote site; (e) the step of said computer control means determining based on instructions included in said control signals whether receiver means at said remote site is operating; and (f) the step of directing, based on the result of said determination step, said information transmission and a selected portion of said control signals to (1) said receiver means and associated computer equipment or (2) a recorder means activated by said computer control means.</p>

Application Claim 143	U.S. Pat. No. 5,335,277, Claim 1
<p>143. A method of outputting a video presentation</p>	<p>1. A method of processing control signals and</p>

<p>at a receiver station including:</p> <p>receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal;</p> <p>passing said received video image to an output device for delivery to a user;</p> <p>detecting said at least one first discrete signal;</p> <p>passing information contained in said at least one first discrete signal to a processor in response to said step of detecting;</p> <p>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</p> <p>responding, at said processor, to processor instructions comprising said organized information, based on said step of organizing;</p> <p>generating a signal based on said processor instructions; and</p> <p>outputting at least a portion of said video presentation based on said generated signal.</p>	<p>controlling equipment at a remote site based on broadcast transmissions including:</p> <p>(a) the step of receiving at said remote site a broadcast carrier transmission;</p> <p>(b) the step of demodulating said broadcast carrier transmission to detect an information transmission therein;</p> <p>(c) the step of detecting and identifying at said remote site control signals associated with said information transmission;</p> <p>(d) the step of passing at least a portion of said control signals to a computer control means at said remote site;</p> <p>(e) the step of said computer control means determining based on instructions included in said control signals whether receiver means at said remote site is operating; and</p> <p>(f) the step of directing, based on the result of said determination step, said information transmission and a selected portion of said control signals to (1) said receiver means and associated computer equipment or (2) a recorder means activated by said computer control means.</p>
--	---

Application Claim 152	U.S. Pat. No. 5,335,277, Claim 1
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</u></p> <p>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one</p>	<p>1. A method of processing control signals and controlling equipment at a remote site based on broadcast transmissions including:</p> <p>(a) the step of receiving at said remote site a broadcast carrier transmission;</p> <p>(b) the step of demodulating said broadcast carrier transmission to detect an information transmission therein;</p> <p>(c) the step of detecting and identifying at said remote site control signals associated with said information transmission;</p> <p>(d) the step of passing at least a portion of said control signals to a computer control means at said remote site;</p> <p>(e) the step of said computer control means determining based on instructions included in said control signals whether receiver means at said remote site is operating; and</p> <p>(f) the step of directing, based on the result of said determination step, said information transmission and a selected portion of said control signals to (1) said receiver means and associated computer equipment or (2) a recorder means activated by said computer control means.</p>

<p>receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and <u>wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	
---	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 157	U.S. Pat. No. 5,335,277, Claim 1
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</p> <p>transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>1. A method of processing control signals and controlling equipment at a remote site based on broadcast transmissions including:</p> <p>(a) the step of receiving at said remote site a broadcast carrier transmission;</p> <p>(b) the step of demodulating said broadcast carrier transmission to detect an information transmission therein;</p> <p>(c) the step of detecting and identifying at said remote site control signals associated with said information transmission;</p> <p>(d) the step of passing at least a portion of said control signals to a computer control means at said remote site;</p> <p>(e) the step of said computer control means determining based on instructions included in said control signals whether receiver means at said remote site is operating; and</p> <p>(f) the step of directing, based on the result of said determination step, said information transmission and a selected portion of said control signals to (1) said receiver means and associated computer equipment or (2) a recorder means activated by said computer control means.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter

station and a receiver station. This differentiates claim 157 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 162	U.S. Pat. No. 5,335,277, Claim 1
<p>162. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of discrete signals, said method comprising the steps of:</u> <u>receiving a video image at a transmitter station;</u> <u>delivering said video image to a transmitter;</u> <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> <u>transferring said at least said first of said plurality of discrete signals to said transmitter; and</u> <u>transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</u></p>	<p>1. A method of processing control signals and controlling equipment at a remote site based on broadcast transmissions including: (a) the step of receiving at said remote site a broadcast carrier transmission; (b) the step of demodulating said broadcast carrier transmission to detect an information transmission therein; (c) the step of detecting and identifying at said remote site control signals associated with said information transmission; (d) the step of passing at least a portion of said control signals to a computer control means at said remote site; (e) the step of said computer control means determining based on instructions included in said control signals whether receiver means at said remote site is operating; and (f) the step of directing, based on the result of said determination step, said information transmission and a selected portion of said control signals to (1) said receiver means and associated computer equipment or (2) a recorder means activated by said computer control means.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 167	U.S. Pat. No. 5,335,277, Claim 1
<p>167. A method of outputting a video graphic presentation at a receiver station including: receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</p>	<p>1. A method of processing control signals and controlling equipment at a remote site based on broadcast transmissions including: (a) the step of receiving at said remote site a broadcast carrier transmission; (b) the step of demodulating said broadcast carrier transmission to detect an information transmission therein;</p>
